Fig. 2 Transient resonance Raman spectra. *a*, Fully oxygenated haemoglobin; excitation 15 ns, 15 laser pulses, 3 mJ per pulse. *b*, Partially photo-deligated haemoglobin; excitation 30 ps, 100 laser pulses, 1.2 mJ per pulse. *c*, Unliganded haemoglobin from stable deoxyhaemoglobin; excitation 15 ns, 20 laser pulses, 3 mJ per pulse. The same spectra were obtained from photo-deligated HbCO .

on the integrity of the protein structure^{26,27}, we suggest that the protein plays its part by acting directly on the charge of the iron atom and does not affect the geometric state of the haem. Furthermore, the protein relaxation process should be influenced by the structural and electronic state of the haem (including the iron ionic state, iron bound or not). This may explain some ambiguities and disagreements between recent electron paramagnetic resonance measurements²⁸, EXAFS data¹⁶ and resonance Raman work^{24,28,29}.

Transient Raman study of CO-haemoprotein photolysis: origin of the quantum yield

J. M. Friedman & K. B. Lyons

Bell Laboratories, Murray Hill, New Jersey 07974

Carbon monoxide and haemoproteins (Fe^{2+}) form ligand-protein complexes that are photodissociated with high quantum efficiency by visible light^{1,2}. By photolysing the CO-protein complex with pulsed laser radiation it is possible to generate transient species with properties which reflect both the nature of the photolytic and recombination processes as well as non-equilibrium protein dynamics. Using a single pulse both to photolyse and examine the sample, we previously reported³ the resonance Raman spectrum of a transient species of haemoglobin (Hb) occurring within 10 ns of the photodissociation of carboxyhaemoglobin (HbCO). Transient species generated by photodissociating HbCO have been intensively studied by using transient absorption spectroscopy covering picosecond^{4–6}, nanosecond^{7–10} and longer time scales^{11–15}. The overlap of the absorption bands related to various species can hamper the extraction of quantitative information from absorption spectra. Nevertheless, progress has been reported, in particular, the results of nanosecond transient absorption studies^{9,10} reported after the experiments described here were well under way. Those results, including re-interpretation of earlier data⁸, led to the suggestion^{9,10} that photolysis of HbCO actually leads to a near-unity quantum yield of a deoxy-Hb species, followed by substantial recombination within 100 ns. We present here definitive evidence from Raman spectra of the 1,350–1,380- cm^{-1} region, where the HbCO and deoxy-Hb species exhibit well separated peaks, that this interpretation is indeed correct. We have also measured accurately the HbCO population as a function of delay time after full photolysis, and thereby measured the kinetics of the recombination process. Our findings bear directly on such questions as geminate recombination and the origin of the difference in quantum yield of photodissociation for HbCO and carboxymyoglobin (MbCO). These two systems exhibit very different quantum yields when strongly pumped in the visible: MbCO undergoes 97% photolysis whereas HbCO undergoes only 45–47% (ref. 15).

The apparatus used was similar to that reported previously³, except that the resonance Raman spectrum was generated by a 10-ns dye laser pulse (Moletron UV 24 and DL 14) fired with

an adjustable delay (up to 1 ms) after the pump pulse from the frequency doubled (5,320 Å, 20 mJ) output of a ND:YAG laser (Holobeam 500 QG). The spectra discussed below were obtained using between 4,100 Å and 4,350 Å (≤ 0.1 mJ) probe pulse excitations. As before³ the spectrum is accumulated by an optical multichannel analyser, based on an SEC Vidicon tube. The sample configuration has been changed to a flowing cell with the temperature and atmosphere of the sample under external control. A more detailed account of the apparatus is reported elsewhere¹⁶. Both Hb and Mb solutions (0.1 mM in haem, pH 7.5 phosphate buffer) were maintained at 10–20 °C under one atmosphere of CO. The solutions were initially degassed and treated with dithionite.

Spectra were recorded covering the region 1,225–1,575 cm^{-1} . The most prominent feature in this spectral region for Soret band excitations is the polarised peak which occurs at 1,357 cm^{-1} for deoxy-Hb, 1,373 cm^{-1} for HbCO and at 1,377 cm^{-1} for HbO₂ with similar values for Mb. The present study will deal only with the behaviour of this peak. A series of typical spectra for Hb and Mb is shown in Figs 1 and 2, respectively. Firing the dye laser before the photolytic pulse (a), we find that the spectrum reflects predominantly unphotolysed material (photodissociation by the probe pulse has been minimised by focusing the beam to a line). Within the first few nanoseconds after photolysis, the HbCO and MbCO peaks have completely disappeared and a peak in the region of the deoxy species has appeared (b). This observation is consistent with previous results obtained using a single pulse^{3,17,18} and using CARS¹⁹. At later times a difference is observed in the two systems. In the Hb system the HbCO peak regains nearly 50% of its intensity (Fig. 1c) within 100 ns of photolysis. On the same time scale (Fig. 2c) no corresponding change is observed in the Mb spectrum. At much later times the expected bimolecular recombination¹³ takes place in both Hb (Fig. 1d–g) and Mb (Fig. 2d–f). The transient deoxy peak is of better quality in the spectra excited with 4,200 Å and its position at early times (< 1 μs) is shifted slightly to lower energy than that associated with the steady-state deoxy-Hb (T) species. This shift is probably due to the effect of the structure of the haem pocket on the porphyrin^{20,22}.

At first glance, the intensity of the deoxy peak in the Hb system (Fig. 1) seems to be constant during the fast recombination process. This suggests that a species may exist after photolysis which is 'silent' in Raman scattering, and which subsequently decays into HbCO. To analyse this possibility more carefully, we used a nonlinear least-squares analysis to fit spectra similar to Fig. 1c–g, at 10 ± 2 °C, to a weighted average of

spectra similar to Fig. 1a, b.

$$S(\Delta\nu) = A_{\text{CO}}S_a(\Delta\nu) + A_{\text{deox}}S_b(\Delta\nu) + B$$

where $S_{a,b}(\Delta\nu)$ represent the corresponding points of the spectra in Fig. 1a, b. The three parameters A_{CO} , A_{deox} and B are varied to achieve a least-squares fit to $S(\Delta\nu)$ over the range shown. The results of this analysis are shown in Fig. 3, where we plot the weighting factors A_{CO} and A_{deox} against delay time. It is significant that, although all three parameters were varied independently, the value of B was consistently insignificant (<5% of the peak) and the sum of A_{CO} and A_{deox} was consistently between 95% and 110%. These results were so striking that we decided to reject the two points (out of 28) for which they did not apply. The quality of the fit was quite good for times below 400 ns. Data were taken at excitation frequencies from 4,350 Å, where the ratio of the deoxy-Hb Raman cross-section to that for HbCO is about 3.0, to 4,150 Å, where it is about 0.3. As shown in Fig. 3, the population values determined by our analysis, in the range studied, did not depend on excitation frequency outside an experimental error of about 10% for delays below 400 ns. Thus, we conclude that (1) for times between 10 and 400 ns, the Raman enhancement does not change appreciably for either species, nor do their respective line shapes; (2) for each ligated haem which appears, an unligated haem disappears; (3) 41% of the photolysed haem groups initially observed at 15 ns after photolysis recombine within 200 ns. A fit to the points under these assumptions, shown in Fig. 3, gives a recombination lifetime of 65 ns for the fast process. The occurrence of such a fast recombination process has also been inferred^{9,10} from transient absorption studies. Note that the absorption lines of the two species are not completely resolved spectrally.

The analysis discussed above was only qualitatively useful beyond 400 ns, because the position of the peak for the deoxy-Hb species begins to shift noticeably at that delay. The deoxy peak moves 3–4 cm^{-1} , to higher energy, between 0.5 and 4 μs delay. The resonant enhancement also evidently increases. (The amount of this increase is a function of excitation frequency, as expected. At 4,200 Å the increase is about 10%). These changes, probably the spectral signature of the initial events

Fig. 1 Raman spectra of HbCO taken at various delays after photolysis with a time resolution of 10 ns. The various traces, shown displaced vertically for clarity, correspond to: a, before photolysis; b, 15 ns after; c, 100 ns; d, 1 μs ; e, 10 μs ; f, 100 μs ; g, 1 ms. The small shifted 'CO' peak in trace b may be due to the presence of a small amount of HbO_2 . Note the reappearance of HbCO in trace c.

heralding the R - T transition in the partially ligated Hb^{22} , caused spurious changes in the population values extracted in the least-squares analysis, and the resulting fits were noticeably poorer. Hence, the results for these later times could not be treated as quantitatively as those displayed in Fig. 3. Nevertheless, the results at early times yield striking evidence that the quantum yield for photolysis of HbCO deviates from 100% due to a recombination of photolysed haems, with a characteristic time of 65 ± 25 ns. Correcting our results for the recombination taking place in the first 15 ns, we obtain an estimated quantum yield of $54 \pm 4\%$ (that is, 46% recombination total). Comparing this with the reported value of the quantum yield of 47% (53% unphotolysed) measured at longer times, we see that the absolute quantum yield for the primary photolysis process (that is, the Fe-CO bond cleavage) is about 90%, a value similar to the total yield observed in MbCO, where the fast recombination does not occur.

Fig. 2 Transient Raman spectra of MbCO analogous to Fig. 1. The traces represent: a, before photolysis; b, 15 ns after; c, 100 ns; d, 1 μs ; e, 10 μs ; f, 1 ms. No significant recombination is observed for times < 100 μs .

The observation of the nanosecond recombination in Hb but not in Mb and the known similarity in electronic properties of the haems in both proteins tend to rule out explanations for the occurrence of this sizeable fast recombination based solely on the electronic properties of the iron porphyrin. On the other hand, there are germane properties of haemoproteins, such as the quantum yield for the photodissociation of the CO-haem complex, which are dependent not only on the specific protein but also on the quaternary structure of a given haem protein¹⁵. Consequently, it seems highly plausible that variation in protein structure about the haem rather than major variations in the electronic state determinants of the photolytic pathway is responsible for the major differences²¹ in the behaviour of photolysed carboxyhaemoproteins.

The rapidity of this process suggests that the recombination process involves photodissociated CO molecules that have remained in the vicinity of the haems, that is, geminate recombination. This interpretation is strongly supported by our observation that the fast recombination is insensitive to the CO concentration (0.02–2 atm). This lack of sensitivity to the CO

Fig. 3 Population weight factors, A_{deox} , A_{CO} , resulting from the least-squares analysis described in the text. The wavelengths in the key denote the dye laser excitation used to obtain the resonance Raman spectra.

concentration was also observed in transient absorption measurements at discrete frequencies¹⁰. In the absorption study it was also found⁹ that the amount of recombination decreased with increasing temperatures. From these dependencies we conclude that the fast recombination is, in fact, geminate in origin.

The deoxy-haem species appears in transient absorption spectra within picoseconds of photolysis⁴⁻⁶. Hence, any geminate recombination mechanism must include some means of trapping the CO molecule in the haem pocket after cleavage of the Fe-CO bond for a time τ of about 65 ns. Furthermore, this trapping, if it involves the Fe ion, must occur in a way that does not produce the HbCO absorption or Raman spectra. It seems likely, then, that the trapping is related to direct interaction of the CO molecule with the surrounding protein. This interaction probably takes the form of CO-binding sites (or potential minima) on the protein. This direct CO-protein interaction, responsible indirectly for the geminate recombination, would explain the protein and conformation dependence of the quantum yield.

The difference between the MbCO and HbCO systems could lie either in the dynamics of escape and recombination from similar sites, or in the existence of different kinds of sites. In either case, the α - and β -chains would be expected to exhibit differences in their behaviour. The conformation dependence of the quantum yield¹⁵ may also be explained on this basis. Furthermore, the proximity of the geminate recombination fraction to 50% in the R conformation strongly suggests that one chain predominantly undergoes recombination and the other does not. Indeed, experiments with isolated chains do indicate differences¹² at 290 K ($QY_{\beta} \approx 8\%$, $QY_{\alpha} \approx 90\%$). However, because this relationship is strongly temperature dependent, it may not hold at physiological temperatures, where the quantum yield for HbCO is much higher, and the geminate recombination is correspondingly reduced.

Thus, we have shown that transient resonant Raman spectra of photodissociated HbCO support the basic features of the suggestions made recently on the basis of transient absorption experiments^{9,10}. The better separation of the transient species in the Raman spectra has made possible a more complete determination of the populations as a function of time after photolysis. Our findings indicate that differences in the quantum yield for photodissociation of carboxyhaemoproteins can originate from differences in geminate recombination rates.

The interaction between protein and water is of fundamental importance for processes ranging from protein folding and enzymatic activity¹ to anhydrobiosis². In this letter we bring together results from diverse types of measurements to give a unified picture of the hydration process for lysozyme. The data come principally from experiments with protein films and powders. The principal aim is to examine the relationship between the sites of water interaction, the extent of coverage, and the enzymatic activity, thus providing a better understanding of the relationship between water and enzyme dynamics³.

Figure 1 describes the results of measurements on the heat capacity⁴, enzymatic activity⁵, IR spectroscopic properties⁶, and diamagnetic susceptibility⁷ of lysozyme powders as a function of hydration level (h , g of water per g of protein).

The appearance of a positive peak at $1,580 \text{ cm}^{-1}$ in the IR difference spectrum (Fig. 1a) indicates the formation of carboxylate species⁶. Apparently, drying the protein below $0.05h$ has produced inversion of the pK order for carboxylic and basic groups, resulting in charge neutralisation by proton transfer. This implies that interaction with water is associated with proton redistribution—that is, normalisation of the pK order with deprotonation of carboxylic acid groups and protonation of basic groups, presumably amino groups, to give the ionisation state found for the protein in solution. A proton redistribution process is expected to produce a rise and fall in the heat capacity, as is observed at $0.05h$ (Fig. 1d).

§ To whom correspondence should be addressed.

The discontinuity in several properties at 0.07h must represent at least changes in water-water and water-protein interactions, because there are effects on the IR spectroscopic properties of both water (Fig. 1c) and protein (Fig. 1a, b). The change in slope of the heat capacity function at 0.07h suggests that the water-protein arrangements have greater freedom above the discontinuity. In this regard, the partial specific heat capacity of the water bound below 0.07h is similar to that of ice or water vapour, while that above 0.07h is greater than that of liquid water, which has twice the specific heat capacity of ice. It is important that the fine structure of the amide I' band is unchanged above 0.07h, and thus significant contributions to the heat capacity from changes in protein conformation can be ruled out⁶.

Fig. 1 Properties of the lysozyme-water system as a function of water content. The correspondence between the vertical bar in the figure and the units of measurement is given separately for each curve. From top to bottom the curves are: *a*, Absorbance at the carboxylate band maximum ($1,580\text{ cm}^{-1}$), measured at 38°C ; units, 0.35 A. *b*, Change in the amide I' band, measured at 38°C as the difference between the negative ($1,690\text{ cm}^{-1}$) and positive ($1,645\text{ cm}^{-1}$) extrema about the isosbestic point of the differential spectrum; units, 0.17 A. *c*, Frequency of the highest intensity maximum of the OD stretching band of adsorbed D_2O , measured at 38°C . The total shift is from $2,550\text{ cm}^{-1}$ to $2,580\text{ cm}^{-1}$. *d*, Apparent specific heat capacity of lysozyme, for 25°C ; units, $0.2\text{ J K}^{-1}\text{ g}^{-1}$. This function is a measure of the excess heat capacity of the system per g protein. *e*, Enzymatic activity, measured at 25°C ; units, $5 \times 10^{-6}\text{ s}^{-1}$. *f*, Diamagnetic susceptibility, measured at 25°C and expressed as differential susceptibility per g of water adsorbed; units, $0.55 \times 10^{-6}\text{ e.m.u. g}^{-1}$. The high hydration limit is equal to the value for liquid water ($0.721 \times 10^{-6}\text{ e.m.u. g}^{-1}$).

The continuous changes in heat capacity and IR spectroscopic properties from 0.1 to 0.2h represent binding of water at amide and carboxylate sites and presumably also other charged or polar sites. Saturation of these sites, if it is complete before significant covering of nonpolar elements, is expected to require^{8,9} about half the water needed for monolayer coverage, as is observed (0.2 versus 0.38h). The polar atoms are largely in the backbone and side-chain amide groups. The change in the amide I' band is a local effect produced by association of the amide group with water and not the result of changes in protein conformation¹⁰.

At 0.2–0.25h the carboxylate and carbonyl sites are saturated (Fig. 1a, b). The full coverage of the hydrogen-bonding sites is reflected in the differential diamagnetic susceptibility, which at this hydration level reaches the value for liquid water. At 0.25h the heat capacity rises (Fig. 1d) and then falls to the dilute solution value at 0.38h. This behaviour must be associated with coverage of the nonpolar elements of the protein surface, in view of the IR spectroscopic results that show saturation of hydrogen-bonding sites at lower hydration. The rise and fall in the heat capacity can be understood as a transition associated with covering of the least-strongly interacting regions of the surface. Statistical mechanical arguments indicate that a transition is expected at high coverage for adsorption of water on a heterogeneous surface¹¹. The magnitude of the 0.25h heat effect indicates that as many as 100 water molecules could be involved⁴.

The appearance of enzymatic activity at 0.2–0.25h (Fig. 1e) coincides with the saturation of the hydrogen-bonding sites and with the beginning of the coverage of the nonpolar regions of the surface. The catalytic activity is not simply reflecting water as a substrate in the hydrolytic reaction, because the dependence of the reaction velocity on water activity is tenth order. The new water arrangements on the protein surface that obtain above 0.25h may be required for catalysis. Spin-label studies⁵ show that these have greater motional freedom.

The apparent specific heat capacity shows no change between 0.38h and dilute solution. Because the heat capacity reflects all equilibria of non-zero enthalpy as well as the heat capacities of the components of the system, we regard this as sufficient evidence for the statement that the changes in thermodynamic properties associated with protein hydration are complete both for the protein and the solvent at 0.38h. This amount of water is barely sufficient to constitute monolayer coverage⁴ and corresponds to 300 molecules of water per protein molecule. Higher hydration is required to establish fully the kinetic properties for the dilute solution state.

We infer that between 0.1h and dilute solution, there can be no substantial change in protein structure. This is concluded from the monotonic behaviour of the IR spectroscopic properties of the amide and carboxylate groups between 0.07 and 0.25h, from the monotonic rise of the enzymatic activity observed above 0.2h, and from the constant apparent specific heat capacity observed from 0.38h to higher levels of hydration.

The following picture of the hydration process emerges from the findings and comments given above. The first water bound interacts with ionisable groups to produce proton redistribution. There is a clear transition in the hydrogen bonding between water and protein and water and water at 0.07h. This probably represents a change in the water molecule distribution about the protein surface, followed by an increase in freedom of the water-protein system. At 0.2–0.25h there is a major event in the hydration process, which is seen most clearly in the heat capacity and which coincides with the onset of enzymatic activity and the reaching of the final value of the response of the system to a magnetic field. Completion of monolayer coverage is at 0.38h, a value substantially greater than that for first observation of enzymatic activity. The protein with monolayer hydration shell must mesh simply with the bulk solvent.

MATTERS ARISING

Age and significance of alluvium in the Windrush Valley

RECENTLY Hazelden and Jarvis¹ reported a radiocarbon date of $2,660 \pm 85$ yr BP for *in situ* roots in the gravel underlying the alluvium of the River Windrush, Oxfordshire. They suggest that this date represents the regional onset of clay deposition following forest clearance. This hypothesis discounts the possible role of channel migration which, although mentioned by the authors, was not discussed further.

Many rivers in southern and eastern England have gravel underlying the floodplain. Such rivers include the Trent, Nene, Great Ouse and Thames, together with many of their tributaries. The underlying gravels are continuous with those gravels lying about 1 m above the floodplain, forming the first or floodplain terrace. The majority of these first-terrace gravels seem to be middle-late Devensian in age², and they represent a phase of aggradation probably caused by increased sediment load during periglacial conditions. As sediment supply decreased, when periglacial conditions ended, downcutting occurred, giving rise to the wide channel now infilled by alluvium.

Deposition of fine-grained alluvium would be expected to have started as the ameliorating climate led to the formation of meandering rather than braided rivers. Dates from the base of the alluvium are highly variable, ranging from 10,000 to 2,500 yr BP (refs 3,4) and probably reflect the time at which the floodplain deposits were last reworked by a migrating meander rather than an ubiquitous change in conditions.

The deposits of the River Windrush^{1,5} are very similar to those found elsewhere and it therefore seems entirely plausible that an alder tree, growing through a pre-existing floodplain with roots in the underlying gravel, should have been eroded by a migrating meander at 2,660 yr BP with no change in sediment supply, climate or base level.

Department of Geology,
Imperial College,
London SW7 2BP, UK

HAZELDEN AND JARVIS REPLY—While this is a possible alternative explanation, it seems to us a less likely one. The truncation of the alder roots is associated with the gravel/clay interface; nowhere in the area have we seen the roots in the clay. Buried A horizons are common within the clay alluvium, and the sequence of deposits is the same over a large area of the floodplain, so it seems that extensive reworking by migrating meanders has not taken place. In view of this and the corroborative evidence from Farmoor we think our explanation more likely.

Trace metals in remote Arctic snows: natural or anthropogenic?

NRIAGU¹ states that "It is encouraging that the ratios of the 1901–10 to the 1971–80 emissions of metals calculated from the data in Table 3 are consistent with the historical changes in rates of trace metal deposition observed in polar ice cores in the Northern Hemisphere". Some of the data cited^{2–4} in support cannot now be considered reliable, and we believe that the remaining data do not support his statement. The historical changes observed in polar ice cores appear much smaller than corresponding changes in worldwide anthropogenic emissions presented by Nriagu in Table 3.

The rate of trace metal deposition is a complex function of many variables, predominantly that of the deposition rate of snow. Reported deposition rates have been calculated from observed metal concentrations and from accumulation rates of snow which have not apparently

changed significantly during the period in question. There is no established theoretical or empirical relationship linking concentrations of metals in precipitation to those in air⁵, but most workers have assumed that the relative abundance of metals in snow reflects the composition of aerosols. Whilst this has been substantiated at the South Pole^{6,7}, recent work has revealed considerable differences in composition between Arctic aerosol and snow at Barrow, Alaska⁸.

Of the data cited by Nriagu, results obtained from a temperate glacier in Norway⁴ contain insufficient information about the local geology and analytical procedures, so that the abnormally high metal concentrations quoted must be treated with caution. The Dye-3 data² for recent snow are now believed^{3,9} to reflect local contamination from the nearby base manned since 1959. Using the data from Camp Century² and Station Milcent³, the ratios of metal concentrations in snow deposited during the periods pre-1900 and post-1960 have been calculated. These values, together with their standard deviations, are given in Table 1. Average concentrations in snow rather than ranges have been considered since the spread of extreme values may in part arise from seasonal variations¹⁰ and maximum values often represent contamination. The resulting ranges are so wide that no meaningful conclusion can be made.

Table 1 shows that the concentration ratios in snow are considerably smaller than the corresponding anthropogenic emission ratios. These discrepancies can be partially explained if the natural emissions quoted as most acceptable by Nriagu are added to the anthropogenic emission figures (last column of Table 1). There is even closer agreement if higher natural emission values (within the limits of values given by Nriagu and others¹¹) are chosen. It is to be expected that a higher proportion of trace elements of natural origin (particularly volcanogenic) will be transported long distances compared with emissions of anthropogenic origin, a major proportion of which return to Earth

Table 1 Comparison of global metal emission data with metal concentrations in Greenland snow

Metal	Anthropogenic emission ratio (from Nriagu's Table 3)	Camp Century snow concentration ratios ^{2*}	Station Milcent snow concentration ratios ^{3*}	Emission ratio including natural sources ¹
	1971–80	Post-1960	Post-1960	1971–80

close to their source¹². Volcanism has been invoked to account for the particularly high proportion of natural emissions in Antarctic snow⁶.

A substantial natural input of trace metals to Greenland snow has been reported by other workers¹³, and a large enrichment of heavy metals in comparison with crustal reference elements has been firmly demonstrated in both ancient and modern polar snows^{13,14}. Until the mechanisms of trace metal deposition are clearly understood, any attempts to assess temporal changes in atmospheric loadings from evidence in ice cores must be tentative.

NRIAGU REPLIES—Landy *et al.* have misinterpreted my report¹. I was careful to say changes in rates of trace metal deposition rather than the ratios in trace metal concentrations in the ice layers. My statement clearly pertains to dF/dt (where F is metal flux rate at each ice layer and t is time), and is quite different from the linear relation, C_1/C_2 (C_1 , C_2 are metal concentrations of dated ice layers) assumed by Landy *et al.* The data tabulated by Landy *et al.* may thus bear no relationship whatsoever to the statement in my paper.

Landy *et al.* have dismissed the data of Jaworowski *et al.*² because “it contained

insufficient information about local geology and analytical procedures”. However, more than a page of this paper was devoted to materials and methods and included the cogent reference to the work on the characteristics of the Storebreen glacier. The high values of metals reported may not be due to sample contamination as such but may instead be related to deposition of long-range transported material from industrial centres of Europe (such as sulphate deposition and acid rains, see refs 3 and 4). In this sense, the Storebreen glacier probably contains a better record of changes in intensities of metal emissions in Europe.

The use of average concentrations of metals in ice layers deposited over a period of several decades or centuries (before 1900) in deriving the data listed by Landy *et al.* is misleading. It assumes that the rate of metal deposition was constant before AD 1900, which is contrary to the available evidence^{5,6}. I have calculated the ranges in the post-1960 to 1800–1900 ratios of reported trace metal concentrations in the ice fields of the Northern Hemisphere (Table A). The maximum and minimum values in reported metal concentrations during 1800–1900 and since 1960 have been used to derive the data listed. Obviously the ranges in the ratios are quite wide and the ratios obtained using my emission data are either within or fall near these ranges. This is ‘encouraging’ considering that the emission data are only order of magnitude estimates anyway.

The contention by Landy *et al.* that the trace metals in Arctic snow are derived mainly from natural sources is probably not valid. Rahn and his colleagues^{11,12} in fact have recently presented rather convincing evidence that the aerosols at widely dispersed Arctic sites of northern Norway, northern Greenland and Barrow, Alaska are strongly pollution-derived, particularly during the winter time. Before that, Chow and Earl¹³ used the isotope ratio method to show that most of the lead in Greenland glacier is of anthropogenic origin. Ancillary evidence in support of the anthropogenic origin of lead deposited in the snow fields of Northern Hemisphere are given by Settle and Patterson¹⁴. Note that the ratios of the present day deposition rates for Pb, Cd, Cu and Zn at Centrale, Greenland and at Dome C, Antarctica are

65, 16, 16 and 91 respectively¹⁵; the ratios of the Pb, Cd, Cu and Zn concentrations in present day surface snow at the two sites are 6.9, 1.6, 1.6 and 9.4 respectively¹⁵. Presumably, the much higher concentrations and deposition rates at the Arctic site vis-a-vis the Antarctic location is related to the fact that most of the anthropogenic emissions of metals occur in the Northern Hemisphere.

It should be emphasised, however, that thorough studies are needed on the deposition mechanisms and on the factors controlling the elemental composition of polar snow and ice before the metal concentrations in the ice layers can be related quantitatively to the atmospheric metal burdens. On this point, I completely agree with Landy *et al.*

BOUSTRON COMMENTS—With regard to the above exchange of views I would like to comment on the available polar ice and snow historical records of the variations of the atmospheric concentrations of the five metals (Pb, Cd, Cu, Zn and Ni) discussed in Nriagu's paper¹, in the remote areas of the Northern Hemisphere during the past few centuries. Data such as those published for a temperate glacier in southern Norway² and quoted by Nriagu are not polar data, so that the only genuine polar historical records presently available for the Northern Hemisphere are those obtained in Greenland. Numerous data have been published on the trace metal content of the successive snow and ice layers deposited in the Greenland ice cap during the past few centuries. Unfortunately, many of these data are probably unreliable because they were plagued by severe contamination problems during field collection or (and) during laboratory analysis. It is very important then to estimate which of these data, if any, are reliable: this can be looked at by a detailed examination of the collection and analytical procedures described by the authors, with special reference to the use of high performance clean rooms and to

Table A Ranges in the post-1960 to 1800–1900 ratios of metal concentrations in the Arctic snow fields

Site	Cd	Cu	Pb	Zn
Milcent ⁷	1–2	—	1–7	1–8
Milcent ^{7,8}	<1–10	—	3–20	1–20
Dye-3 ⁹	—	—	9	—
Dye-3 ¹⁰	10–600	1–100	—	<1–40
Camp Century ¹⁰	<1	1–7	—	—
Camp Century ⁶	—	—	<1–>12	—
Jotunheimen Mountains ²	<1–68	—	<1–6	—

blank estimates both for field sampling and laboratory analysis.

Concerning the five metals discussed in Nriagu's paper, reasonably reliable Greenland data seem to be available only on the variations of the concentrations of Pb, Cd and Zn during the past 800 yr (refs 3, 4). On the other hand at present there seems to be no reliable Greenland data on the past variations of the concentrations of Cu and Ni. The reliable Pb, Cd and Zn data are shown in Fig. 1 for the past 300 yr; they do not include the Cd and Zn data published by Weiss *et al.*⁵, which have been shown recently^{4,6} to be erroneously high (by up to 2–3 orders of magnitude for Cd) probably because of severe contamination problems.

The interpretation of the variation profiles shown in Fig. 1 to assess man's global impact on the low atmosphere in the remote areas of the Northern Hemisphere is, however, still questionable for various reasons: (1) the scarce data available do not provide continuous variation profiles; (2) they have been obtained in several widely separated geographic sites; (3) some of the concentrations measured in the recent surface layers (post-1960 data) could be erroneously high because of local contamination problems in the vicinity of the Greenland stations; (4) there are still doubts on the efficiency of the decontamination procedures⁴ used to clean the deep ice core samples whose analysis has produced most of the pre-1900 available data; (5) for the years 1880–1960, which are the most interesting to assess man's impact, there are no Cd and Zn data, and only few Pb data; (6) the variation profiles could have been influenced by the arrival of volcanic aerosols emitted by the eruptions of the near Iceland volcanoes or by major eruptions which occurred in the world, such as Agung eruption (1963)^{7,8}; (7) the impurity content of Greenland snows could be influenced strongly by local crustal sources associated with the large ice free coastal areas of Greenland⁶; (8) there is no clear demonstration available that there are no chemical-fractionation processes at the air-snow interface in Greenland, such as the ones documented recently in Alaska⁹, which could lead to misleading interpretations of the snow and ice records in terms of atmospheric records.

Figure 1 suggests, however, that there has been no definite increase trend for Cd and Zn concentrations during the past 300 years. This is also the case for Pb before approximately 1940; after this date, a significant but limited increase of the concentrations of Pb seems to have occurred (about threefold increase). From the available data it seems, therefore, that the concentrations of Pb, Cd and Zn in Greenland snow and ice have not increased markedly during the past few centuries except probably for Pb since 1940, then suggesting that there has been no significant increase of the atmospheric

concentrations and then of the fallout fluxes F of these metals in the remote areas of the Northern Hemisphere since the beginning of the industrial revolution, except probably for Pb after 1940: the changes in anthropogenic emissions of these trace metals calculated by Nriagu¹ (from 1850–1900 to 1971–80: 19.5-fold increase for Pb, Cd and Zn) are then clearly much higher than the very limited historical changes in the fallout fluxes F of these metals observed in the remote polar areas of the Northern Hemisphere. (At a given polar site, the tropospheric fallout flux F of a metal during a given year is

Fig. 1 Greenland: available reasonably reliable data on the concentrations of Pb, Zn and Cd in the successive snow and ice layers deposited since 1700. The different symbols correspond to separate sampling locations (O, Milcent; Δ , Camp Century; +, 45 km ESE from Camp Century; x, 80 km ESE from Camp Century).

calculated by glaciologists as $F = CA$ where C refers to the mean measured concentration of the considered metal in the snow or ice layer deposited during this year and A is the annual snow accumulation during this year. In Greenland, A has been shown not to have changed markedly during the last centuries¹⁰. Note that at present it seems impossible to derive from the scarce Greenland data shown in Fig. 1 any useful estimate of the time derivative dF/dt to which Nriagu claims to refer in his reply, and then to check whether the historical changes of dF/dt support the changes in anthropogenic emissions he calculated or not.

The available snow and ice Greenland data suggest strongly that the influence of human activity on the trace metals content of Greenland snow and ice, and therefore probably on the trace metals content of the low atmosphere in the remote areas of the Northern Hemisphere, is actually negligible for Cd and Zn and makes only a limited contribution for Pb: the high atmospheric enrichments observed presently for these metals in various remote areas in the Northern

Hemisphere^{11,12} are then very likely linked with natural processes such as volcanism.

However, it would be highly desirable to confirm and to complete the scarce Greenland data, through a cooperative analysis of new samples to be collected for this purpose, especially to get detailed continuous data on the trace metals content of the snow and ice layers deposited in Greenland during the past 100 yr.

Finally, I would like to comment on another point: the comparison¹¹ of the present day Pb, Cd, Zn and Cu concentrations measured in surface Greenland snows at Centrale⁶ with those measured in surface Antarctic snows at Dome C¹³. Present-day Greenland concentrations are higher than Antarctic concentrations probably principally because of the very different geographical locations and meteorological regimes of Greenland and Antarctica, and not only because of the fact that more than 90% of anthropogenic aerosols are emitted in the Northern Hemisphere¹⁴ as stated by Nriagu: Antarctica is indeed much more remote from any aerosol sources than Greenland, which is located near the North American continent, and is moreover protected from the influence of mid-latitude aerosol sources by the 50°S polar convergence.

From the present day surface concentrations at Dome C and at Centrale, and from the annual snow accumulation at these two sites, it is possible to get estimates of the present day fallout fluxes of Pb, Cd, Zn and Cu (ref. 11) in the central areas of Antarctica and Greenland: the fallout fluxes calculated at Centrale, Greenland are much higher than those obtained at Dome C, Antarctica, as pointed out by Nriagu. But this strong difference is certainly mainly related to the fact that the annual snow accumulation at Centrale ($34.3 \text{ g H}_2\text{O cm}^{-2} \text{ yr}^{-1}$) is one order of magnitude higher than the annual snow accumulation at Dome C ($3.5 \text{ g H}_2\text{O cm}^{-2} \text{ yr}^{-1}$).

Polydipsia after intracranial injections—a property of NGF or a contaminant?

INTRACRANIAL injections of 2.5S NGF in adult rats have been shown to induce intense polydipsia¹. Subsequent studies from other authors confirmed this finding and, in addition, gave evidence of increased appetite for sodium solutions². The authors of this last article call attention on the similarity between these effects and those elicited by intracerebral renin injections. Previous work from this laboratory in collaboration with the Department of Pharmacology, University of Heidelberg³, showed that isorenin activity is present in 2.5S NGF preparations and is separated only after laborious additional purification steps. Thus, NGF prepared with the same method as that used for studies on induced polydipsia and sodium appetite still showed considerable amounts of renin-like activity. According to Cozzari *et al.*³ it was necessary to perform three further carboxymethyl-cellulose chromatographies after the usual procedure to prepare 2.5S NGF, in order to eliminate all renin-like activity previously detectable.

In view of the many effects which have been recently claimed to be caused by NGF intracranial injections^{4,5}, it seems essential that whenever high doses of NGF are needed to produce a given effect, it should be clearly established that the preparations are entirely free of contaminants. This precaution is of particular importance since NGF has been found to be tightly bound in mouse salivary extracts with other proteins endowed with enzymatic or other biological activities.

LEWIS ET AL. REPLY—Levi-Montalcini is right to draw attention to the possibility that the effects of NGF on the central nervous system may be mediated by portions of the NGF complex other than the β subunit. As we pointed out in our report¹, the marked similarity between the effects of intracranial injections of 2.5S NGF and renin on thirst and sodium appetite suggested that the effects of 2.5S NGF might be mediated by the cerebral isorenin-angiotensin system. Activation of this system is an exceedingly potent stimulus to thirst² and sodium appetite³. We have since established that

7S NGF⁴ has similar effects on thirst and sodium appetite, and that both 2.5S⁵ and 7S NGF produced renin-like pressor responses when injected intravenously in intact and nephrectomised rats⁶. The doses of these NGF preparations needed to produce pressor responses are comparable to those used in the standard *in vitro* NGF bioassay⁷ and considerably less than the doses of NGF reported to induce growth in the sympathetic ganglia of newborn mice⁸. The pressor responses to 7S and 2.5S NGF were abolished by the angiotensin-converting enzyme inhibitor SQ 14,225, the angiotensin-receptor blocker saralasin, and NGF antiserum⁶. The same procedure also blocked the effects of these NGF preparations on thirst and sodium appetite⁹. Immunogenically pure β -NGF subunit¹⁰ from the mouse submandibular gland was devoid of pressor activity and had a much smaller and more variable effect on thirst and sodium appetite than other preparations of NGF⁶.

Our demonstration that NGF-induced thirst and sodium appetite are mediated through the formation of angiotensin II (AII) raises the possibility that other effects of NGF preparations are similarly mediated. For example, we have recently found that intracranial administration of renin, like 2.5S^{11,12} and 7S NGF, results in a marked increase in the activity of ornithine decarboxylase (ODC) in brain and liver⁶. These increases in ODC activity in response to renin and NGF are blocked by pretreatment with SQ 14,225 and are therefore dependent on the formation of AII⁶. The AII-dependent induction of ODC in the liver following NGF administration is due to activation of the pituitary-adrenal axis, as the induction is blocked by either hypophysectomy or adrenalectomy¹². Otten *et al.*¹³ recently reported that systemic injection of 2.5S NGF, the purity of which was controlled by SDS-polyacrylamide gel electrophoresis¹⁴, caused a rapid increase in plasma ACTH and corticosterone levels. However, systemic or central administration of AII also causes an increase in plasma ACTH and corticosteroid levels^{15–17}. Therefore, activation of the pituitary-adrenal axis following NGF administration may be due to the presence of a renin-like enzyme in the NGF.

Our findings complement those of Cozzari *et al.*¹⁸, who reported that NGF preparations from mouse submandibular gland are associated with a renin-like enzyme that can only be removed after much additional purification. Whether this renin-like enzyme or other enzymes^{19,20} should be regarded as integral components of mouse submandibular gland NGF complexes has not been resolved. However, unless renin-free preparations of NGF are used, the use of angiotensin antagonists such as SQ 14,225 and saralasin should be considered

obligatory, particularly when a biological effect attributed to NGF is known to be produced by renin or AII.

Evolution by gene duplication in insecticide-resistant *Myzus persicae*

THE simple model of “a succession of tandem duplications of the structural gene”, proposed by Devonshire and Sawicki¹, cannot account as it stands for the apparent regularity of the variation in enzymatic activity of the organophosphorus (Op) insecticide resistance associated esterase (E4¹ or RAE²) observed in specimens of the peach potato aphid, *Myzus persicae*, from different laboratory stock clones, because the esterase does not have the same electrophoretic mobility or phenotype in all the clones compared.

The enzyme from the predominant Op resistant clone in British field populations³ (E4(MS1G) or RAE(+)²) stains after electrophoresis in two close but distinct bands, the rear band being fainter and staining more slowly². Aphids with this electrophoretic phenotype, but with higher enzymatic activity on the gel, have also been collected in the field², and these could have arisen by duplication of the E4(MS1G) gene, although other explanations are also possible, for example, that they are homozygous for E4(MS1G), or that they are a mutant in which E4(MS1G) has become more resistant to denaturation in gel assay

conditions. But the high activity enzyme in the laboratory clone French R and the very high activity enzyme in the highly Op-resistant glasshouse clone PirR (electrophoretically identical to that in the highly resistant clones from northern England and western Scotland⁴) both stain after electrophoresis in a single band with an electrophoretic mobility slightly but distinctly different from E4(MS1G) and from each other.

Because of this electrophoretic distinctiveness it is unlikely that either of these high activity mutant esterases could have arisen by a duplication of the E4(MS1G) gene, or that the higher activity esterase (E4(PirR)) could have arisen by a duplication of the gene for the lower (E4(French R)). A more reasonable explanation would be that E4(MS1G), E4(French R) and E4(PirR) arose independently in separate mutations in different Op-susceptible aphids.

4. Devonshire, A. L., Foster, G. N. & Sawicki, R. M. *Plant Path.* **26**, 60–62 (1977).

DEVONSHIRE REPLIES—The simple model of “a succession of tandem duplications of the structural gene” is based on the measurement of insecticide hydrolysis¹, and not simply on the subjective assessment of electrophoresis gels stained for naphthyl acetate-hydrolysing enzymes. The enzyme, E4, has been shown to be identical in susceptible and resistant aphids, and differences in activity are a direct consequence of the production of more of the same enzyme¹.

Esterase E5 (which probably corresponds to ‘the satellite’² to E4) is present in MS1G and French R, but not in the other five clones examined¹ and seems to occur only in untranslocated variants. Any association of this band with E4 is speculative, and our studies have shown that it plays no part in insecticide hydrolysis. Baker suggests that the six specimens from two sites, in which “the electrophoretic band (E4) appeared³ to be slightly retarded in mobility and without a satellite (E5?)” are associated with glasshouses. We have never detected such decreased mobility of E4 in slightly resistant variants among the several thousand insects examined from the field and glasshouses throughout the UK. The biochemical and toxicological significance of this putative electromorph has not been investigated, and it has little bearing on our conclusions. Although very resistant aphids (with 32 or 64 times as much enzyme) appear to have E4 with slightly lower mobility, on dilution the enzyme reverts to the characteristic mobility either when run alone or when coelec-

trophoresed with E4 from susceptible insects. It is therefore an artefact of the electrophoresis probably arising from the larger amount of protein present.

In view of the convincing biochemical evidence, and lack of ‘electrophoretic distinctiveness’ of E4 in the seven variants examined, we believe gene duplication to be the most likely cause of the overproduction of E4 by resistant aphids. This, however, does not preclude hitherto undiscovered mutations at this structural locus.

Spider feeding behaviour optimises dietary essential amino acid composition

GREENSTONE¹ showed that dietary mixing occurs in the lycosid *Pardosa ramulosa* (McCook) and claimed that the spiders optimise their intake of essential amino acids. He took the optimal proportions of amino acids to be those present in the spiders and estimated the ingested nutrients from the amino acid composition of ‘appropriate extracts’ of the prey. I suggest that the extracts he used were inappropriate so that the data cannot be used to test the hypothesis that they forage optimally for essential amino acids.

The appropriate extract used by Greenstone was prey haemolymph “because spiders do not consume their prey intact and therefore do not ingest skeletal material” (see Table 2 of ref. 1). However, spiders pour digestive fluids onto their prey and ingest the fluid products and the haemolymph but discard the cuticle. In *Tegenaria atrica* Koch these digestive fluids contain a wide range of proteolytic enzymes as well as esterases and carbohydrases². A similar range of digestive enzymes must be expected in all spiders.

Except for the haemolymph, the distribution of amino acids in insects is poorly known but the information available shows no correlation between the amino acid composition of insect protein and that in the free pool amino acids³. In addition the amino acid composition varies between tissues as well as between sexes⁴. Consequently the amino acid composition of ingested material will reflect that of both the haemolymph and of those tissues digested externally. The proportion of each tissue digested will vary because spiders consume different amounts of individual prey items according to, *inter alia*, disturbance, prey type, and hunger and/or prey density. The relationship between the amino acid content of prey haemolymph and the food ingested needs

to be established before the hypothesis can be tested.

W. F. HUMPHREYS

School of Biological Sciences,
Bath University,

4. Chen, P. S. *Monographs in Developmental Biology* Vol. 3, *Biochemical Aspects of Insect Development* (Karger, Basle, 1971).

GREENSTONE REPLIES—As Humphreys intimates, the most appropriate extract for the dietary studies is not an easily extractable fraction, but rather the difference between the total amino acid composition of the insect and that which remains in the carcass after the spider has fed upon it. At the time the amino acid studies were begun it was not possible to initiate a feeding study. Large stocks of the insects, however, were on hand, from which two types of extracts were potentially available: haemolymph alone, which might underestimate the spiders’ amino acid consumptions, and macerates of whole insects, which might overestimate them. I chose to risk underestimation because the spiders’ evolutionary history has predisposed them to having low prey utilisation efficiencies.

Pardosa species are small and live in open habitats¹; this exposes them to heavy density-independent mortality. *P. ramulosa* spiderlings generally have a high ballooning frequency (my unpublished data), which is a correlate of habitat instability^{2,3}. Open and unstable habitats are r-selecting, and among the expected traits of r-strategists is low food utilisation efficiency⁴. *Pardosa* species have been shown to have lower prey utilisation efficiencies⁵, and jumping spiders to feed for less time on each prey item⁶, when food is abundant, as was the case in the study area during my field work⁷. These facts suggested that the spiders would be more apt to take only haemolymph than to consume all of the extractable amino acids.

The use of haemolymph has the additional advantage that material from a large random sample of an insect population can be pooled, thereby averaging out some of the age and sex differences in amino acid composition.

BOOK REVIEWS

Food for thought

G. Curzon

BEFORE the 1970s most neurochemists (stimulated by current ideas on biochemical regulation) were probably more interested in brain enzymes than in the substrates they acted on. Consequently, the availability of these substrates to the brain was given relatively little attention. Also, it was thought that, except in severe malnutrition, the brain controlled its nutritional intake so that this was appropriate to its needs. But in the past decade emphasis has shifted, especially with regard to neurotransmitter synthesis. The change began with studies on how brain synthesis of the transmitter 5-hydroxytryptamine (5HT) is controlled. Tryptophan hydroxylase, one of the two enzymes required for 5HT synthesis, is rate-limiting but normally well below saturation with its substrate, tryptophan. This is an essential amino acid, mammals are completely dependent on dietary sources and it is found that normal dietary changes of tryptophan availability to the brain can affect how much of the transmitter is made there.

These findings have led to an explosion of research activity in which Wurtman and his group have played a major role. This interest is strongly reflected in the series so that many chapters describe how dietary constituents get to the brain and their effects on transmitter synthesis therein. Indeed, the whole of Vol. 5 derives from a symposium on the effect of choline supply on brain acetylcholine synthesis. Apart from this, five chapters, distributed between Vols 1, 3 and 4, deal wholly or in major part with dietary or other extracerebral influences on transmitter synthesis. Thus, in Vol. 1, Pardridge describes how amino acid availability to the brain is regulated and Ordóñez similarly discusses folic acid derivatives and choline. Volume 3 contains a chapter by Growdon on dietary neurotransmitter precursors and their use in the treatment of brain disease. Another chapter by Sourkes is on other nutritional factors that may affect transmitter synthesis. Volume 4 includes a chapter by Guroff on how inborn errors of extracerebral metabolism of amino acids and other substances alter the nutrition of the brain.

Nutrition and the Brain. Edited by R.J. Wurtman and J.J. Wurtman. Five volumes. (Raven: New York.) Vol. 1. *Determinants of the Availability of Nutrients to the Brain*, pp.336, 1977, \$29. Vol. 2. *Control of Feeding Behavior and Biology of the Brain in Protein-calorie Malnutrition*, pp.323, 1977, \$29. Vol.3. *Disorders of Eating. Nutrients in Treatment of Brain Disease*, pp.314, 1979, \$29. Vol. 4. *Toxic Effects of Food Constituents on the Brain*, pp.232, 1979, \$23. Vol. 5. *Choline and Lethicin in Brain Disorders* (edited by A. Barbeau, J.H. Growdon and R.J. Wurtman), pp.474, 1979, \$42.

Another major area is covered in Vol. 2 and the rest of Vol. 3. These chapters are on normal and pathological aspects of feeding: control of eating (Vol. 2, Lytle); metabolism in obesity and anorexia nervosa (Vol. 3, Cahill *et al.*); medical aspects of these disorders (Vol. 3, Bruch); a critical analysis of claims for megavitamin therapy in mental disease (Vol. 3, Lipton *et al.*). Most of this material is on effects of disturbances of volition towards eating. The brain obviously has a causal role in these disturbances although little is at present known about its nature. The rest of Vol. 2 is on protein-calorie malnutrition — a primarily involuntary disorder. Here the important questions concern effects of the reduced food intake on the human brain, their reversibility and their behavioural consequences. As Shoemaker and Bloom point out in their chapter on the effect of undernutrition on brain morphology, early undernutrition might conceivably affect subsequent behaviour and other brain functions by numerous mechanisms. While present evidence for specific mechanisms may well be unclear this does not diminish the enormous potential social importance of research in this area. Other chapters in Vol. 2 are on biochemical (Nowak and Munro) and behavioural (Pollitt and Thomson) effects of protein-calorie malnutrition. Background material on the dietary patterns of numerous human societies and of non-human primates is given in Vol. 1 by Gaulin and Konner.

Tables 7–9 are particularly fascinating.

Volume 4 is largely on toxic effects of food constituents, i.e. food additives and hyperkinesia (Lipton *et al.*), glutamic acid (Garattini), peptides (Zioudrou and Klee), alcohol (Tabakoff *et al.*). These effects range from the obviously important but imperfectly understood (alcohol) to the probably unimportant (glutamic acid), although it is necessary to keep in mind the conclusion of the chapter on hyperkinesia that there is probably no food or drug without some toxicity to some individuals.

Volume 5 is substantially different from the other volumes, which each contain four to six chapters, as it contains 38 contributions to a symposium. Topics include choline, lecithin and acetylcholine metabolism, and the pharmacology of the cholinergic neurone. The main focus is on the extent to which functional brain cholinergic activity is affected by dietary supplements of choline and lecithin and whether these compounds can be used to treat various disorders of the central nervous system. There seems to be some evidence that large dietary supplements may alleviate tardive dyskinesia but not other dyskinetic states such as Huntington's chorea and dopa dyskinesia. Patients with presenile dementia, though they have a major defect in brain acetylcholine synthesis, show disappointingly little response. In general, the therapeutic trials described were of a preliminary nature. Neither of the studies on tardive dyskinesia was done 'blind'. The chapters by Ansell and Spanner, Haubrich *et al.* and Karczmar are particularly useful, as they provide a biochemical and pharmacological background for assessing the (on the whole less substantial) clinical papers which take up much of the volume.

The series in general is strongly recommended. It is attractively produced and well indexed. The overall clarity of presentation must indicate much hard editorial work. One may expect these volumes to be a major influence on future research in their field. □

G. Curzon is a Professor of Neurochemistry at the Institute of Neurology, University of London, UK.

Methods of polarographic analysis

Emil Paleček

Polarography of Molecules of Biological Significance. Edited by W. Franklin Smyth. Pp.328. (Academic: London and New York, 1979.) £22.60, \$52.

THE sensitivity of polarographic (voltammetric) determinations has greatly increased in the past 10-15 years. While the limits of detection of organic and inorganic substances reached by classical d.c. polarographic methods were usually around 10^{-5} M, using modern differential pulse anodic stripping voltammetry, inorganic substances can be determined at concentrations down to 10^{-10} M. Cathodic stripping voltammetry is becoming a very useful tool in the analysis of certain organic compounds at concentrations as low as 10^{-8} – 10^{-9} M; and differential (derivative) pulse polarography operates at concentrations of 10^{-6} – 10^{-8} M for both organic and inorganic substances. This remarkable gain in sensitivity, together with the commercial availability of reliable polarographic analysers, has resulted in a steady increase in the number of analysts using modern polarographic (voltammetric) methods. This process, sometimes called the 'renaissance of polarography', is, however, not yet accompanied by the predictable abundance of books concerning the theory and application of modern polarographic methods. Smyth's book is thus a valuable acquisition for analytical chemistry libraries.

The first two chapters of this book describe unit processes in polarographic (voltammetric) analysis of organic substances such as choice of method, preparation of the sample, selection of a proper supporting electrolyte, cell and electrodes, derivatization and complexation procedures, and so on. Further chapters deal with the application of polarographic methods in pharmacy and pharmacology, basic medical and environmental sciences, and agriculture. Polarographic determinations of various groups of substances are in general compared with determinations by means of other methods; and the advantages of the polarographic analysis of certain types of compounds are stressed. It is shown that differential pulse polarography is highly suitable for the determination of pharmaceutical products and other substances containing nitrogroups; and sulphur-containing substances (many of them representing trace foreign materials which pollute the environment) can be determined at low concentrations by cathodic stripping voltammetry.

The book is well-written; it has not,

however, managed to escape entirely without errors; for example, in the paragraph on purine and its derivatives (Chapter 5) it is stated that pyrimidine and cytosine are oxidizable at graphite and mercury electrodes. It follows from the cited paper (G. Dryhurst and P. J. Elving) that both substances are non-oxidizable. In spite of the fact that a relatively extensive literature on polarography of nucleic acids exists, only two original papers are cited in Chapter 6, one of them incorrectly; review articles concerning this topic are

completely ignored.

Minor errors do not, however, substantially diminish the significance of this book, which can be confidently recommended to all analytical chemists dealing with determinations of biologically important organic substances, and especially to those of them who have come in contact with polarography in the past. □

Emil Paleček is Head of the Department of Macromolecular Biophysics at the Institute of Biophysics, Czechoslovak Academy of Sciences, Brno, Czechoslovakia.

Interstellar dust

D.E. Brownlee

Cosmic Dust: Its Impact on Astronomy. By Peter G. Martin. Pp.266. (Clarendon/Oxford University Press: Oxford, 1979.) £9.

PETER MARTIN'S *Cosmic Dust: Its Impact on Astronomy* is not an encyclopaedia of what is known about extraterrestrial dust. It does not cover Moon dust, Mars dust, comet dust, Venusian smog or plumes from Io's volcanoes. It is a book which concentrates on star dust and is a comprehensive coverage of current information and ideas concerning dust in the interstellar medium. Interstellar dust is a basic form of matter in galaxies and is the common form of most elements heavier than helium that are not currently residing in stars. Interstellar grains are produced in gaseous regions surrounding stars; they experience an evolutionary existence as tiny astronomical bodies and are eventually destroyed by super novae shocks or interactions with stars. They are somewhat of a nuisance, as they totally obscure most of our Galaxy in visual wavelengths and cause extinction, reddening and polarization in observable objects. However, as Dr Martin enthusiastically points out, dust grains are fascinating bodies important to a variety of disciplines in astronomy.

The book's first five chapters deal with the interaction of dust and radiation in the interstellar medium. These chapters cover fundamental theory as well as up-to-date observational and laboratory data. Topics include radiation transfer, calculation and laboratory measurement of particle cross-sections, extinction of optical and X-ray wavelengths, polarization, and scattering. The fifth chapter deals with the properties and modelling of reflection nebulae. In addition to providing the reader with a good background on the interaction of light and dust, the author also interprets existing observations in terms of limitations they place on the nature and distribution of interstellar dust.

Chapters six and seven discuss the theory and observation of thermal emission from grains. This includes far-infrared from the

Galactic plane and the properties and structure of circumstellar dust shells. Chapters eight and nine deal with the distribution of dust in the Galaxy, the nature of dust clouds and interactions of dust with the interstellar environment. Specific topics include radiation pressure, spin, charge, sputtering, molecule formation, alignment and dust in dark clouds, and H II regions, planetary nebulae and the Solar System. The coverage of most of these topics is somewhat introductory and does not go into considerable depth. In chapter ten the significance of spectral signatures such as the 2200 Å and 10 µm features are discussed as indicators of grain composition. Also discussed are the importance of cosmic abundances and abundances in interstellar gas as constraints on grain composition. Chapter eleven reviews the evolutionary processes and timescales experienced by dust. Basically this chapter is concerned with the formation of refractory cores and volatile mantles and their stability in changing interstellar environments. The final chapter contains a brief section on dust in other galaxies and an intriguing discussion about properties and possible observations of dust between galaxies.

In the preface the author states a goal to give the reader basic tools and to discuss concepts underlying current research. This he does quite well. A careful reading of this book will provide the reader with a broad-based background in both the theory and current state of observation of interstellar grains. In general the book can be highly recommended, although there are some minor drawbacks. The organization is such that certain topics are diffused through widely separated parts of the book. It sometimes is difficult to answer a specific question without reading most of the book. Although it provides a good background, this is not a handy source book for quick reference. The most serious drawback in the opinion of this reviewer is the lack of formal references. At the end of each chapter is a list of "further reading" but these are not true references that refer to specific points in the text. This continually raises a question of credibility. The reader is apparently expected to accept the written word as dogma. The lack of conventional references also makes it difficult for the

reader to go into a specific subject in more depth than covered in the text. Annoying but less serious problems are with the figures. Most of the line drawings are excellent and were printed in a readable standard format. A small number of drawings, however, are direct computer plots with tiny difficult-to-read labels and needless excess zeros behind the decimal point. Many of these are multifunction plots where individual lines are very difficult to distinguish from each other. Only a few plots are really terrible but they are certainly not for the farsighted. Some

of the letters are less than $800\mu\text{m} \times 500\mu\text{m}$, some of the plotted lines are actually less than a $100\mu\text{m}$ in width, and in places both plotted lines and figure borders totally disappear. The continuous tone photographs have poor tonal quality similar to newsprint.

Cosmic Dust is a comprehensive up-to-date book that will be of significant value to anyone working in fields involving interstellar grains. It contains a good coverage of the theory, observations and current state of understanding of dust in the interstellar medium. For someone just

getting into this interdisciplinary field it contains a wealth of suggestions for important future work. For the corner librarian this book will be a headache. Although *Cosmic Dust* is the first *Cosmic Dust* devoted entirely to interstellar dust, it is the third book with a jacket label of this title published in the past 15 years. □

D.E. Brownlee is Associate Professor of Astronomy at the University of Washington, Seattle, and Associate in Geochemistry in the Division of Geological and Planetary Sciences at the California Institute of Technology, Pasadena.

Forest ecosystem

D.T. Streeter

Pattern and Process in a Forested Ecosystem: Disturbance, Development and the Steady State Based on the Hubbard Brook Ecosystem Study. By F.H. Bormann and G.E. Likens. Pp.253. (Springer: Berlin, Heidelberg and New York, 1979.) DM42, \$23.10.

As the sub-title indicates, this book describes the work of the Hubbard Brook Ecosystem Study in northern New England. The authors' objective is to provide an integrated picture of the structure, function and development of an area of northern hardwood forest and to set their data against current concepts of ecosystem dynamics. In effect, this book is one of the most complete accounts of secondary woodland succession following clear felling so far to be produced.

The authors propose a four-phase biomass accumulation model of woodland development of reorganization, aggradation, transition and steady state. This differs from the familiar smooth-curve biomass accumulation model of Odum in that the initial 'reorganization' phase of up to 15 years is a period of net loss in biomass when total ecosystem respiration exceeds GPP, as is also the transition phase which precedes the final 'steady state', when total biomass oscillates about a mean. Most of the book is inevitably concerned with a discussion of the quantitative characteristics of the 'reorganization' and 'aggradation' phases as these have been the subject of the long-term study. Here can be found a wealth of data on biomass accumulation, productivity, hydrological and mineral cycles, species diversity and evolutionary strategies. The discussion of the 'transition' and 'steady-state' phases is necessarily speculative as no examples of primaevial forest survive in New England and the authors estimate that in the absence of external catastrophic events it takes about 300 years for the steady-state phase to be reached by natural developmental processes.

Many authors in the last twenty-five years have questioned the classical Clementsian view of 'climax' vegetation, insisting that it represents no more than an unrealizable abstraction. This is based on the assertion that natural succession is inevitably truncated somewhere in the aggradation phase (of the present authors) by cyclical catastrophic events such as fire or wind-blow. This issue is fully examined in the light of the available historical and ecological evidence, and the authors conclude that so far as their study area is concerned the fire-rotation periods are far longer than would be needed to prevent natural development reaching the steady-

state phase and that climax forest would indeed have been a reality in pre-settlement times.

Throughout the book there are undertones of a Clementsian 'supra-organism' philosophy but these are not permitted to become unduly obtrusive. The authors freely acknowledge that much more is owed to A.S. Watt's concepts of pattern and process in vegetation, an approach that will meet with a sympathetic hearing from most British ecologists. □

D.T. Streeter is Reader in Ecology in the School of Biological Sciences, University of Sussex, Brighton, UK.

Sediment studies

R.C. Selley

Coastal Sedimentation. Edited by D.J.P. Swift and H.D. Palmer. Pp.339. (Dowden, Hutchinson and Ross: New York. Distributed by Academic: New York and London, 1979.) \$34, £22.50.

In the words of Professor Fairbridge, Editor of the *Benchmark Papers in Geology*, the philosophy behind the series is "one of collection, sifting and rediffusion". The basic concept is to republish selected seminal papers on a chosen topic in their original form (with minor excision) enveloped in editorial comment.

This is designed to overcome the problems of a scientist trying to delve into original literature only to find that the important references are diffused through many journals, or that, in the case of the newer centres of learning, runs of journals are of too short a span to contain vintage papers.

The first of these problems is particularly acute in the field of coastal sedimentation which is reviewed in this particular benchmark volume. This is a topic which is of interest to a wide range of scientists, engineers and even ecologists and conservationists. These range from geographers, geologists, civil and

hydraulic engineers to marine ecologists and sailors. Thus, it is not surprising to find that the papers in this volume are reprinted from periodicals as diverse as the *Journal of Waterways and Harbors Division of the American Society of Engineers*, the *Bulletin of the Georgia (USA or USSR) Academy of Sciences*, the *Bulletin of the American Association of Petroleum Geologists*, the *Beach Erosion Board of the US Army Corps of Engineers*, and a symposium volume published by the National University of Mexico. Few scientists can claim to have such eclectic interests as to monitor all these publications. They must be too busy reading to do any work if they can.

The book reprints a total of twenty papers which have been arranged in four groups. Each group is preceded by several pages of comment and introduction by the editors.

The papers in Part I are concerned with the coastal equilibrium profile. They begin with a bowdlerized version of Fenneman's classic paper of 1902, twenty pages having been omitted from the original thirty-two. This is followed by several papers written by US geologists in the nineteen-sixties. Part II is concerned with coastal deposits, reprinting five papers describing certain North American beaches and shelves. Part III is headed "Studies of Fluid Motion" and reprints five papers ranging from "Bottom Currents during Hurricane Camille" to "Wind-Driven and

Thermohaline Circulation over the Continental Shelves'. Part IV contains four papers on the theme "Studies of Substrate Response". These present observations on the erosion, transportation and deposition of sand in selected coastal areas. The book concludes with author and topic indexes.

From the preceding account it is clear that the titles of this volume should perhaps not have been so catholic as *Coastal Sedimentation* but rather 'North American Sandy Coasts'. No two scientists would produce the same top-twenty list of significant papers on coastal sedimentation. Nevertheless, the concentration on sandy coasts

of the USA is surprising. Only two papers deal with non-US coasts, one in Mexico, the other in the North Sea. There are no papers on carbonate coasts, either of such classic areas as the Bahamas or the Persian Gulf. Neither are there any papers on deltas, or on muddy coasts, such as the tidal flats of the North Sea made famous by Dutch and German workers.

A review of previous benchmark volumes shows that coastal sedimentation has already been done in various disguises — No.3, Spits and Bars, No.9, Barrier Islands, No.30, Holocene Tidal Sedimentation, and No.39, Beach Processes and Coastal Hydrodynamics. Perhaps some of

the omissions noted in this book have appeared previously. A volume entitled 'Benchmark Papers of Benchmark Papers on Coastal Sedimentation' is perhaps now overdue.

It is hard to see this particular book appealing to many individual scientists. Perhaps only the newest and wealthiest of libraries may consider purchasing it. Since the text has been prepared by photographically copying the original papers, some in typescript, the cost of £19.15 seems rather high, perhaps even a benchmark. □

R.C. Selley is Reader in Petroleum Geology at Imperial College, University of London, UK.

Glucocorticoids at work

G. S. Boyd

Glucocorticoid Hormone Action. Edited by J. D. Baxter and G. G. Rousseau. Pp.638. (Springer: Berlin, Heidelberg and New York, 1979.) DM 118, \$64.90.

THERE is interest in the mode of action of the steroid hormones in attempts to discover at the molecular level how these hormones work. Investigation of the way in which sex hormones act is simpler since it is possible to identify specific target tissues. However, the glucocorticoids present a difficult challenge because these steroids have such widespread effects, and the tissue response to the hormone depends upon the nature of the tissue.

The late Gordon Tomkins played a significant part in attempts to discover how the glucocorticoids work, and it is fitting that this volume should be dedicated to the memory of this brilliant researcher.

The book is a series of short essays on various phases of the possible mode of action of glucocorticoids. The editors have contributed an introductory chapter, various other chapters and a concluding generalizing chapter updating some of Tomkins' concepts and placing these views in a modern setting. The volume has over 600 pages and is divided into 34 chapters so that any one contribution is fairly short. The contributors appear to have been adequately briefed by the editors because there is a reasonable degree of continuity throughout this multi-author review. The book contains accounts of the transport and uptake of corticoids by cells. Various aspects of the association of the hormones with the cytosolic receptor molecules are expounded, the structure-activity relationships are explored, and the translocation into the nucleus and the nature of the nuclear binding of the glucocorticoids are considered. The grey areas on the activation of the genetic

apparatus in the nucleus are critically reviewed and the role of the glucocorticoids as important factors involved in the induction of tyrosine aminotransferase and tryptophan oxygenase is considered. It seems a pity that the chapter on tryptophan oxygenase is one of the shortest in the book. In separate chapters various authors deal with the mode of action of corticoids on fibroblasts, thymocytes, leukaemic cells, pituitary cells and leukocytes. There are also contributions on the role of glucocorticoids in glycogen metabolism,

lipid metabolism, insulin action and the stability of lysosomes. The editors have made a bold attempt to obtain coverage of as many aspects of corticoid action as possible in this sizeable book. Naturally this has resulted in a degree of overlap in places. Nevertheless this is a good book which will be a useful source to all who wish to have ready access to information on the action of the glucocorticoids up to about 1977-1978. □

G. S. Boyd is Professor of Biochemistry at Edinburgh University Medical School, UK.

Collision theory

A. D. Buckingham

Atom-Molecule Collision Theory. Edited by R. B. Bernstein. Pp.779. (Plenum: London and New York, 1979.) \$57.50.

IN the last 20 years there has been an enormous growth of interest in the study of molecular collisions by beams techniques. In 1977 the American Chemical Society was able to arrange a symposium entitled "State-to-State Chemistry". The advances of electronic and vacuum instrumentation have produced a wealth of information on atomic and molecular cross-sections covering elastic, inelastic and reactive scattering. This volume is intended as a guide to scattering theory for experimentalists in the field of molecular collisions. It is restricted to atom-molecule collisions, for which the theory is at present tractable.

The first chapter is by Bernstein himself. It provides an interesting and informative overview of the development of the beams technique and of the current state of experiment and theory. The second chapter, by H. F. Schaefer III, reviews the *ab initio* computation of potential energy surfaces; the third, by P. J. Kuntz, is on semiempirical potential surfaces for collision theory. The analysis of elastic

scattering is discussed in great detail by H. Pauly for central forces, and by S. Stolte and J. Reuss for non-central forces. Inelastic scattering theory is covered in chapters by J. C. Light, D. J. Kouri, D. Secrest, M. D. Pattengill and W. R. Gentry. Non-adiabatic electronic transitions are described by M. S. Child, and reactive scattering by J. C. Light, R. E. Wyatt, D. G. Truhlar, J. T. Muckerman and D. A. Dixon. There are chapters on collision-induced dissociation by D. J. Diestler and P. J. Kuntz, and the final contribution is by R. D. Levine and J. L. Kinsey on the application of information theory to molecular collisions. There are 22 chapters and author and subject indexes, making up the 779 pages.

The book has some of the usual problems associated with a multi-author volume; however these are not grave, and the overlap and the changes in notation are not really a serious disadvantage. As compensation the spread of authorship, including many distinguished contributors, has provided a breadth of coverage that no single writer could have achieved. The book is highly recommended to those for whom it was intended — experimentalists in the field of molecular scattering. It will also be valuable to a wider group of physicists and chemists interested in the dynamics of molecular collisions. □

A. D. Buckingham is Professor of Chemistry at the University of Cambridge, UK.

17 April 1980

Conserve energy, conserve cash

"YOU can't run Britain like a grocer's shop!" said an exasperated trade union leader recently. He was referring not only to Mrs Thatcher's humble economic education, but also to the government's uncompromising arithmetic policy of restricting current expenditure by taking pennies, regardless, off every item.

The only lines in Britain's shop to remain untouched have been ones close to Mrs Thatcher's heart: defence, law and order, and nuclear power — the latter benefiting from a £10 billion spending programme over the next decade. Energy conservation, on the other hand, she has been content to leave to market forces.

Officials in the Department of Energy are not impressed, according to an internal memo recently leaked to the media, which draws attention to "a sharp and visible contraction in the government's conservation programme". The problem, says the memo, may be that "apart from improving the building regulations, we have in fact no proposals on the conservation front which do not call for extra resources either in terms of money or staff. At the present time, both are clearly not starters."

Another leaked document — this time minutes of a meeting of the 'Committee of Ministers on Energy Conservation' — shows that the junior minister concerned with conservation, Mr John Moore, is unhappy with Prime Ministerial attitudes. "Mr Moore" say the minutes "felt the committee could achieve little without the evidence of a political will from [Mrs Thatcher]".

The UK has not, in the past, come out well in international comparisons of measures taken to conserve energy, and it seems that the country is slipping further down the league. In its orgy of cutting spending, the government has:

- scrapped plans for 14 regional home energy saving advice centres (saving £500,000 a year)
- announced the closure in June of a scheme to help businesses improve inefficient boilers, insulate buildings, and install or improve combined heat and power schemes (saving £25 million over 2 years)
- halved the budget for assisting individuals to insulate their homes (saving £12.5 million).

But conservation needs more than the price mechanism alone. As the Secretary of State for Energy, Mr David Howell, said last year, there has to be "sensible and sensitive" government intervention or the energy conservation programme will be unbalanced. Pressure is

rising on Mrs Thatcher to take cognizance of this. Last month a syndicate of ten organisations including the Electricity Consumer's Council, the increasingly important Parliamentary Liaison Group for Alternative Energy Strategies, and other bodies with a long record of serious concern with the energy scene, requested that the Select Committee on Energy should turn its attention to the effect of spending cuts on the conservation programme; and it seems likely that it will follow their lead. The committee should do so, as a matter of priority, for the leverage on primary energy consumption of a pound spent on conservation is probably very great.

This is to say that a pound spent on conservation can save more energy than a pound spent on production can produce. According to some estimates, the factor can be as high as three. And judging by French plans (reported in *Le Monde*) to save 10 million tonnes of coal equivalent by spending £6 billion in industry, the French government itself — despite its ambitious nuclear programme — is aware of these relativities.

David Howell, opposition spokesman on energy, told *Nature* this week "Britain spends peanuts on conservation. We want a step-change in attitude". And the attitudes we need to change are those which see energy production as a matter of investment, but energy conservation as a matter of giving grants. The Central Electricity Generating Board, the Gas Board, the National Coal Board actually advertise to encourage us to use more energy: 'cook electric' advertisements appear regularly on television despite the fact that electric heating consumes three times the *primary* energy of the equivalent gas heater or cooker. Power stations are only one-third energy efficient.

As the Department of Energy memo has it: "If the funds spent on conservation replace the same or greater amounts spent on supply, should it matter that they are going to private companies or individuals rather than, say, the CEEB or the NCB?" Certainly not if the true blue objective of an energy policy is to ensure that the economy is unrestrained by constraints on energy supply. The economy can be released from energy costs more rapidly, more continuously (with less lumping of capital, unlike the £1 billion per nuclear reactor), and most likely, more cost-effectively. If you conserve energy, Mrs Thatcher, you conserve cash; and you conserve it rapidly, with payback times that are within the lifetime of your parliament. Is that not sufficient political incentive? □

The Antarctic

Managing krill in the Southern Ocean

THROUGHOUT next month, the thirteen signatories of the Antarctic Treaty will meet in private in Canberra, Australia to negotiate a convention to control the exploitation of krill — commonly regarded as the Antarctic's most immediately exploitable resource. Krill are small shrimp-like creatures which thrive in great abundance in the extraordinarily nutrient-rich cold waters of the Southern Ocean. They are central to maintaining the ecological balance of the Antarctic because they feed on abundant phytoplankton and in turn are fed on by many larger animals; in particular they form the staple food of whales. They are also increasingly being recognised as a potential source of protein for man. Hence the need for a convention which controls man's exploitation in such a way as to be non-discriminatory between different nations and at the same time maintain the local eco-system.

The Antarctic Treaty states have been negotiating the 'krill convention' — Convention on the Conservation of Antarctic Marine Living Resources in secret — for several years. Next month's meeting is hoped to be the last: agreement on the text of the convention should be reached, although ratification could take up to ten subsequent years.

The success of the convention, however, will also depend upon how acceptable it is to other nations not involved in its negotiation but nevertheless interested in reaping some of the benefit of the opening up of new fishing grounds. In particular, several developing countries have expressed fears that the convention only takes into account the interests of the

Antarctic Treaty signatories and other countries which are technologically capable of fishing in the extreme conditions of the Antarctic. The secrecy of the negotiations has not helped to dispel such fears and some observers, in particular the authors of a report published by the International Institute for Environment and Development (IIED)* last week, believe that agreement on the convention may spark off a wider international debate on the rights of access to the fishing grounds.

Reaching some sort of agreement just among the Antarctic Treaty signatories, however, will not have been easy. The key problem has been how to cope with the territorial claims of some nations to large slices of the Antarctic continent together with 200 mile-wide coastal strips of sea. Those signatories who have not laid claim to land do not recognise the claims of the others. The problem has therefore been to work out a 'bifocal' approach which leaves open the question of sovereignty over coastal fishing grounds.

The political problems of negotiating the convention are certainly great — but there are also many scientific problems to be solved before a system of good management for the Southern Ocean can be established. As yet there are no reliable estimates of the amount of krill which could be caught annually on a sustainable basis. There is also insufficient information on the interaction of different species living in the area.

The scientific problems implicit in the krill convention are different from those associated with other fisheries agreements

because of the nature of the convention's prime objective — the conservation of marine living resources. This is a totally new approach to fisheries control according to Dr John Beddington of York University who helped the IIED prepare its report. Previous agreements have mainly been concerned with the optimization of harvesting by man.

Although Dr Beddington regards the spirit of the convention on conservation as worthy, he is critical of its scientific approach. In particular, it does not take into account the fact that the net greatest annual increment in a population can be achieved only by removing its predators. In the case of krill this would mean killing whales — a contradiction of the convention's aim of allowing depleted whale populations to recover.

The IIED report recommends alterations to the wording of the convention to eliminate this contradiction. It also suggests that the scientific committee which is to be set up under the convention to provide scientific information, should maintain close links with independent scientists. However, the BIOMASS (the Biological Investigation of Marine Antarctic Systems and Stocks) programme, managed under the aegis of the International Council of Scientific Unions, should remain independent from the scientific machinery of the convention, it says. It should supply independent scientific information, free from any political constraints.

Energy

France plans one third nuclear energy by 1990

A confident forecast by the French Ministry of Industry has predicted that by 1990 France will have cut its dependence on oil to one third of its primary energy demand. It will do this, says the ministry, mostly by a dramatic ten-fold increase in the use of nuclear power, but also through contributions from gas and renewable energies — particularly solar and geothermal. The renewable contribution must increase four-fold in the next ten years to meet the ministries' targets.

France already makes considerable use of hot springs for household heating. All renewable resources (other than hydro) together now contribute only 1.5% of France's annual 323 million tonnes of coal equivalent energy demand, but, says an official communiqué of the council of ministers "certain renewable resources will come to maturity" in the next decade.

These projections considerably exceed those, say, of the UK, where energy

minister David Howell told the Select Committee on Energy recently that "the contribution from renewable sources in the year 2000 might be up to 10 mtce. My department now considers that this is, if anything, an overestimate". 10 mtce would be 2.5% of total energy use in 2000.

UK nuclear projections are also much smaller, a doubling to 9% of demand by 1990, compared to France's 30% by the same date. France must build one reactor every two months to reach its target.

According to *Le Monde* (4 April) the government expects that a £6 billion investment in energy conservation in industry by 1990 will save 10 mtce per year.

Moreover to encourage those living near the sites of projected nuclear power stations to accept their lot, electricity supplies will be set 12 to 17% cheaper for those living "in the vicinity" of the power station.

However not all are happy with the

plans. *Le Monde* quotes M. Michel Rolant, national secretary of the giant trade union CFDT, as saying that while it is desirable to reduce dependence on oil "it is dangerous to make this objective dependent on the imposition of electrical energy on all domains other than transport". The plans imply that in 1990 42% of French primary energy will be converted to electricity, 73% of that being produced by nuclear power stations. At present about 30% of French primary demand goes to electricity generation.

Moreover, said Rolant, France is taking a formidable bet on the good performance of the 66 or so nuclear reactors it will need in operation by 1990.

The cost of this programme — £26 billion according to Rolant — "is so large that it will make it impossible to follow a serious programme of energy conservation, or of the development of renewable sources . . ."

Robert Walgate

BIOGEN, the European-based genetic engineering firm, has had 600 "very good quality" applications for 18 post-doctoral positions in its new Geneva laboratory, Biogen's President, Robert Crawthorne, said last week. The applications come from throughout the world, but it seems likely that one third of the posts will be filled by applicants from continental Europe, one third from the UK, and one third from the US.

"The numbers we are looking for won't drain the pool of available talent" said Crawthorne "but we're looking for the best". Other companies may have had greater difficulty in recruiting, but Biogen has had something special to offer, he said: a chance to work with a scientific board of ten top academics in molecular biology (seven in Europe and three in the US) and "strong and open" links with the universities.

Biotechnology

600 apply to Biogen

Biogen is also planning greater links with European companies, particularly in chemical, petrochemical, and process engineering, said Crawthorne. The first cooperative agreement is expected shortly. "We already have a strong European shareholding: 36%, with 41% in the US and 23% in Canada. But we are not looking for shareholders any more." Rather, Biogen wants to learn from relevant industries what might be the most profitable products to develop with genetic engineering. "We've got expertise in recombinant DNA" said Crawthorne. "The problem is knowing what line to work on."

Biogen has found it very profitable to work with the US pharmaceutical company, Schering Plough, to whom it has licensed interferon production based on the successful cloning and expression of the leucocyte interferon gene by one of Biogen's scientific board, Professor Charles Weissman of the University of Zurich. "We want to extend such links" said Crawthorne, in Europe and elsewhere.

On interferon, he said Biogen was nine months from producing enough for clinical trials. A number of laboratories may undertake pilot plant production, including Professor Brian Hartley's laboratory at Imperial College, London, but decisions on such matters would be undertaken in consultation with Schering Plough. However, there were still a lot of hurdles, particularly over yields and purification.

Robert Walgate

Soviet Union

Moscow seminar meets

EARLIER this week, several non-Soviet scientists gathered in Moscow with about 50 of their Soviet colleagues for the fourth annual "International Conference on Collective Phenomena". These conferences, which are held outside the usual rigid framework of scientific exchanges, grew out of the weekly "Sunday Seminars for Refuseniks", which began in 1973 to provide some kind of intellectual life for Jewish scientists who, having applied for a visa for Israel, found themselves denied professional employment.

Under their restricted conditions of work, without access to libraries, laboratories, computers and the like, it is, inevitably, the mathematicians and theoretical physicists who have the best chance of producing meaningful research. The majority of scheduled papers, therefore, were of a mathematical nature. Indeed, the hosts of the conference, Viktor Brailovskii and his wife Irina, are themselves both mathematicians.

One of the participants, Aleksandr Ioffe, since losing his academic post in 1977 has published several papers in foreign journals, including the *Transactions of the American Mathematical Society* and the *Comptes Rendus* of the Académie Française. In February, 1980, his foreign colleagues held a two-day mathematical symposium in his honour at Imperial College, London, where all but one of the papers were developments of Ioffe's work.

Ioffe, unfortunately, is something of an exception among the refuseniks, most of whom can have little contact with the scientific community abroad. The "Collective Phenomena" conferences (as opposed to the more domestic seminars) were founded

precisely to overcome this feeling of isolation. This year's seminar was sponsored by the UK Institute of Physics, the New York Academy of Sciences, the French Physical Society, the French Institute of Chemistry and the Norwegian Physical Society, inspired, one may assume, by feelings of scientific solidarity rather than the hope that any major new research would be presented there.

The same solidarity, since the conferences began, has encouraged several western scientists each time to make the journey to Moscow, and to present papers of their own. Under Soviet conditions,

organizing an "independent" scientific meeting is liable to run foul of the authorities. Although some intending participants were refused visas, those who actually reached Moscow did not meet with the particular brand of bureaucracy directed at Dr Anthony Kenny, Master of Balliol College, Oxford, last weekend. His lecture, at the underground "Patocka University" in Prague (which met in the flat of Dr Julius Tomin, the dissident philosopher) was interrupted by the security authorities, on the grounds that his visa had been given for tourism, not for addressing other scholars. □

Spaceflight record-holder in orbit again

VALERII Viktorovich Ryumin holds the current record for orbital flight (175 days). His return last week to Salyut-6, where he established this record last year, has caused certain speculation abroad that the Soviets might be preparing a manned mission to Mars.

Such a mission, in fact, would conflict with all "classical" Soviet projects for space exploration. These, following Tsiolkovskii, the "father of Russian

cosmonautics" envisage the establishment of a permanent orbital station as a necessary preliminary to any deep-space mission. Such a station, it is understood, would be staffed by "several tens" of male and female crew and scientists for shifts of several months at a time. At least for this century, it is understood, lunar and planetary exploration will be left to the much cheaper automatic rover vehicles.

Nevertheless, Soviet space-medicine experts are showing considerable interest in the biological effects of long-term space-flights. Last month, Academician Oleg Gazenko told TASS that the most important result to date was that no significant organic changes had been revealed which might limit the duration of future flights, and that people could work in space for six-month periods.

No doubt Ryumin, with last year's record-breaking flight to his credit, as well as a brief mission in October 1977 aboard Sayuz-25, will prove an especially interesting "subject" — albeit a somewhat serendipitous one — during his current flight on Salyut-6. For, so far from being part of a Mars-preparation programme, he was, according to TASS, only included at a very late stage, when the original candidate, Flight Engineer Lebedev, injured his leg during final training.

Vera Rich

United Kingdom

18% photoefficiency claimed in BP energy research prize

FIXED photochemical energy amounting to 18% of visible light has been claimed by one of the recipients of a new energy research prize last week. The figure compares favourably with the electrical efficiency of solar cells, and is so far beyond the 3% normally regarded as the maximum achievable by plants that some specialists are highly sceptical about it.

The prize — £13,000 — comes from the oil multinational British Petroleum, which announced a £1.5 billion a year capital investment programme in its annual report published last week. "In the future" says the report "an increasing proportion of new investment, research and enterprise will be directed to activities additional to oil and gas". The BP energy prize is considered to be a way, said a BP spokesman, "to begin to get in on the act" on increasingly interesting energy research in the universities. But BP will not claim ownership of any of the results.

BP has awarded £39,000 to be divided between three groups from four UK universities. Similar awards will soon be made in ten other countries: Germany, France, Belgium, Denmark, Holland, Switzerland, Greece, Portugal, Canada and New Zealand. After a year's research, reports from the three groups in each country will be considered, and a national winner selected — who will receive a second year's grant and a cash prize of £5,000. These winners will also be considered by an international panel for an international energy prize of £10,000 to be awarded in July 1982.

The UK winners of the first leg are: Professor S J Pirt of Queen Elizabeth College, London, to develop an algal bioreactor for fixing solar energy; Drs H A O Hill of Oxford and I J Higgins of Kent Universities to improve the efficiencies of fuel cells powered by enzymatic reactions; and Dr R P Howson of Loughborough University to develop optical coatings for improved heat retention by windows. The prizes were awarded by a panel of five drawn from the Royal Society and the Fellowship of Engineering.

Professor Pirt hopes to build a 0.5m² collecting area 'unit' bioreactor, which would be deployed in multiples over a solar collecting field. The collecting surface will be tubular, and carry a continuous culture of *Chlorella* fed by ammonia, salts, and 100% CO₂ ("which" says Professor Pirt "we have discovered is not toxic, contrary to expectations").

The system has been developed in the laboratory. The next stage involves scale-up, and the application of microprocessor control to adjust nutrients and flow rates for varying sunlight intensity.

"Our target is to fix 14% of solar energy incident on the field", Professor Pirt said last week. "We have reached 18% photoefficiency in the laboratory" he claimed. Asked if this was not a very high figure, he said there had been no reliable and consistent data for photosynthetic efficiency. "Figures vary by a factor of four". (Pirt has published his results in *J. Chem. Tech. and Biotech.* 30, 25-34; 1980).

Photosynthetic processes were not at their most efficient at the CO₂ levels present in air, said Pirt. It had proved crucial to provide pure CO₂ to the organism "despite the fact that the books say more than 5% is toxic".

Pirt is "quite confident" that the capital costs of the reactor can be brought below those of competing solar technologies, such as solar cells.

One potential advantage of his closed system — where all external factors other than sunlight and temperature can be closely controlled — is that evolved oxygen can also be collected, and would become a by-product of the process. Moreover collected energy — in algal biomass — would be automatically stored, unlike the electrical energy from solar cells.

The biomass could be fermented to methane to provide natural gas; but fixed nitrogen would have to be recovered if the process were to be overall energy efficient. So "there are a number of other biotechnologies to be appended to this system", said Pirt, "before it is complete".

However, other biomass specialists are highly critical of Pirt's results. One pointed out that the currently accepted, "rock-hard" photosynthetic pathway proposed by Dr Robin Hill of Oxford 20 years ago required 8 photons to fix one CO₂ molecule. This leads to a theoretical maximum energy efficiency of 12%; in practice the record is sugar cane's 3%. But Pirt claims 18%, with a mixed culture of his alga and three heterotrophic bacteria.

"Pirt has claimed that one can produce 150 tonnes per hectare per year, but the best practice anywhere else is 30 to 50," said the biomass specialist. "He is doing biomass a fantastic disservice by making these claims" he said.

Pirt said last week that the accepted photosynthetic pathway "lacked any sound energetic data in support of it". His data "implies that we must look at what is wrong with the pathway" he said. "The gaps in our knowledge of it are really enormous. Otto Warburg [Nobel Laureate for medicine, 1931] always claimed that 4 photons per carbon was the correct figure. Others claim 12."

Robert Walgate

Hungary

Paks power station secured in concrete

HUNGARY'S nuclear power stations at Paks, the first generating set of which will go on stream in 1981, is so safe that not even an earthquake presents any serious danger. So said MP Miklos Vida, recommending a new nuclear energy bill to the Hungarian National Assembly last month. On behalf of the parliamentary committees which had dealt with safety questions, Vida noted that "the nuclear power station in the Armenian SSR which resembles the Paks power station easily withstood the force 5 earthquake . . . of 1976; according to estimates it can withstand force 9 earth movements".

Nor, said Vida, is there any fear of a nuclear explosion. "The system of construction of our nuclear power stations is such that it is a physical impossibility for a chain reaction to get, so to speak, out of hand". The only possible danger would be from "harmful radioactive materials finding their way into the environment". And "all necessary measures" have been taken to guard against this. The spent fuel "which represents the greatest source of radiation", will be stored "for some time", then sent back to the Soviet Union for reprocessing.

The remaining waste (liquids with a "high radiation content" and "discarded installations and parts") will be sent to the "isotope cemetery" established in a lenticular clay deposit near Puesto-oksizilagy, already used for radioactive wastes from industry and medicine.

For the Energy Ministry, Deputy Minister Gyula Szeker spoke of current fears regarding nuclear power, stressing that the western nuclear debate was encouraged by political, commercial and other interests which used "the revulsion felt for nuclear weapons" to "create a mood of opposition".

What Szeker did not mention was that the plans for the Paks power station depart from the standard Comecon doctrine that concrete containment vessels are unnecessary, and a capitalist ploy to raise costs. However "safe" the reactor, the Hungarians, it appears, will not neglect a little extra protection.

This somewhat more realistic approach to safety was also reflected in the speech of Imre Markoja, Minister of Justice. He admitted that even when all safety requirements are met "there can be some damage". Matters of responsibility and indemnity, he said, are therefore covered by the Bill. Although damage "due to exceptional events" in the course of operation of the reactor and the transport of nuclear materials is the least likely to occur, it is, however, the most dangerous. Indemnification in the case of damage, would be guaranteed by the state.

Vera Rich

NEWS IN BRIEF

French data systems sabotaged

PROGRAMMED tapes were stolen and fires were set at computer installations in Toulouse by two anti-computer groups last week. The urban guerilla group Direct Action claimed it had removed material "destined for use by the secret services" from the Toulouse offices of Philips Data Systems which it would later release. The second attack, a fire set at the rival computer company, CII-Honeywell-Bull, was claimed in a letter to *Liberation* by a group of "computer technicians well placed to appreciate the dangers to society," calling themselves the Committee to Liquidate or Neutralise Computers. The attacks followed a French government announcement of its plans to issue tenders for extra facilities to expand telematic memory banks for industrial, official and public use.

Jailed South African physicist in court

DR Renfrew Christie, the Oxford-trained nuclear physicist made his first court appearance last week to hear charges that he gave information about South Africa's nuclear programme to banned organisations. Christie, aged 30, has been jailed and held incommunicado without access to lawyers or friends under Section 16 of South Africa's Terrorism Act since his arrest shortly after he returned to take a job at the University of Cape Town last January. He is accused of intending to pass information about the location of South Africa's secret nuclear test sites, and a plan of the layout of the nuclear power station at Koeberg, to the African National Congress and the South African Christian Institute, two banned opposition groups. The trial will continue this week.

AGR plans approved

IN a reversal of her previous decision, Prime Minister Margaret Thatcher has been persuaded to approve plans for the construction of two British made advanced gas cooled reactors as part of the UK's £10 billion nuclear energy programme.

The Central Policy Review Staff and the Department of Industry argued strongly that the British nuclear industry could not develop competitively if the Prime Minister's preference for the American-built pressurised water reactor excluded the AGR. At stake are 3,000 AGR-dependent jobs in boilermaking, pipe and valve manufacturing, and engineering. Capital costs for the two proposed plants, at Heysham in Northwest England, and Torness in Scotland, have risen by 40% to \$2.8 billion in the past year, partly as a

result of increased public demands for safety. The current reactor design has several new safety features, including an enlarged reactor diameter for easier inspection and repair, and extra fuel channels to permit the reactor to maintain full power while operating at less corrosive lower temperatures. The plans also include a spherical concrete containment vessel instead of the cylindrical one.

Fewer Britons die at work

FEWER people were killed in accidents at work in the UK in 1978, according to the Health and Safety Executive Report* for 1978/79. The reduction in deaths — 498, compared with 648 in 1974 — is attributed to a greater concern about hazards at work and better prevention resulting from the 1974 Health and Safety at Work Act.

But fatalities among coal mining and railway workers show a disturbing upward trend. Mine deaths increased from 40 in 1977 to 63 in 1978; those on the railways stood at 48 for 1978, 14 higher than the average figures for recent years.

Approximately 20% of the HSE's total expenditure of £49 million was spent on research, testing and scientific support services for the year in question says the report. Extramural funding accounted for £2.6 million, of which two thirds were devoted to safety in the nuclear industry and to occupational health. Extensive research into the safety of pressurised water reactors and the hazards of exposure to plutonium were studied, safety procedures for genetic engineering were developed and the possible toxic or carcinogenic effects of a number of substances encountered in the workplace were investigated.

*Health and Safety Commission Report 1978/79. Available from HMSO £1.75.

UMIST moves into biotechnology

THE University of Manchester Institute of Science and Technology (UMIST), in a move to become involved in biotechnology, has appointed its first Professor of Applied Molecular Biology. Dr Paul Broda, whose expertise is in the field of bacterial plasmids, will take up the post in the revamped Biochemistry Department of UMIST this September.

UMIST plans to back up the appointment of Dr Broda with a number of other new posts so as to assemble a team that will carry out fundamental research in areas of molecular biology that have potential industrial applications. One particular area of interest will be in antibiotic production from the streptomycetes. Another will be in the use of bacteria to derive end products of commercial value from lignin, a major waste product of the pulp industry.

Report says 55,000 UK smokers die each year

ON World Health Day last week a report issued under the auspices of the World Health Organisation warned of the risks of smoking, and singled out the UK as the worst sufferer. Some 55,000 there die prematurely each year as a result of smoking, says the report, compared with an over 18 annual death rate from all causes of 650,000. Some 41% of adult Britons are regular smokers; one in ten of these will die prematurely of causes directly attributable to smoking and one in four from diseases in which smoking is a major factor.

A study published last week by *Mintel*, a market research magazine, showed that while the number of cigarettes smoked in Britain fell slightly, from 125.9 billion, to 125.7 billion, from 1977 to 1978, the weight of cigarette tobacco smoked rose 10% from 197 million lb to 218 million lb. *Mintel* attributes this to the increasing proportion of sales taken by king-sized brands (10% in 1975, 50% in 1978 and a projected 70% in 1981). This rise in turn is attributed to the adoption in 1978 of EEC-wide tax rules, which favour larger cigarettes.

Academy recommends cut in formaldehyde exposure

CONSUMER exposure to formaldehyde gas, in particular that resulting from the use of urea formaldehyde (UF) foam for house insulation, should be reduced to the "lowest practical concentration" to avoid its irritant effects, according to a panel of the National Academy of Science.

In a report prepared for the US Consumer Protection Commission, the Academy's Committee on Toxicology refers to two European studies, one carried out in West Germany and the other in Denmark, as evidence that "there is no population threshold for the irritant effects of formaldehyde in humans."

The CPSC says that it has received more than 600 complaints from consumers living in homes insulated with UF foam. Reported symptoms range from eye and skin irritation to breathing difficulties, persistent nosebleeds, and nausea.

The Commission adds that the Academy report will help it to develop regulatory standards for consumer products containing formaldehyde. Both the commission and the formaldehyde industry are particularly concerned about the results of recent tests on laboratory rats carried out by the Chemical Industry Institute of Toxicology, which, although not yet completed, already show that 20 per cent of rats exposed to formaldehyde have developed an unusual form of nasal cancer.

FEATURES

Let there be light!

The recent growth of conservative religion in the US has injected new vigour into attacks on the teaching of evolution. **David Dickson** reports from Atlanta, Georgia

MORE than a hundred years after the publication of Charles Darwin's *Origin of Species*, it comes as a surprise to discover that almost half the adult population of the US believes itself to be directly descended from Adam and Eve.

Yet fifty years after a Tennessee courtroom witnessed the public ridiculing of divine creation, creationist beliefs remain as strongly held as ever.

The debating skills of Clarence Darrow in the famous Scopes 'monkey' trial of 1925 may have temporarily taken the wind out of the creationist sails. But today both supporters and critics agree that the creationist movement is growing in both strength and confidence buoyed by a rising tide of conservative ideology that is rapidly becoming a powerful force in American politics.

Many schools throughout the country, for example, are now required to teach creationist beliefs in parallel with evolutionary theory. And in at least six states — including Illinois, Florida, and New York State — legislatures are discussing bills which would make such practices compulsory.

Emotions on the issue run high. Most scientists continue to treat the creationist movement with derision and scorn. "These people are using glib salesmanship to sell an academic snake-oil for the general population" says Dr William Mayer, Director of the Biological Sciences Curriculum Study in Boulder, Colorado.

In the south and mid-west, however, the reaction is different. Here support for an absolute morality has strong appeal, basing itself on a literal interpretation of the Bible.

These regions have been fertile ground for creationist organisations which, in the words of Dr Henry Morris, director of the California-based Institute for Creation Research, seek to "reverse the dangerous drift of our country and its educational system into humanism, socialism, amorism and atheism".

Nowhere has the debate been fiercer than in Atlanta, Georgia. Last month the state legislature narrowly failed to approve a bill requiring that, wherever evolution is taught as part of a biology course in state schools, equal time should be given to creationist theories. Passed by the Senate,

God creates light: a creationist's view of evolution

the bill failed in the House of Representatives in the closing minutes of the last legislative session.

The state Department of Education had argued strongly against the bill, largely on the grounds that details of the curriculum should be left to local school boards. And among other critics the bill attracted the attention of the national 'atheist' organisation which had been responsible for having school prayers declared in violation of the Constitution.

The explicit involvement of the atheists has been a red rag to conservatives such as Judge Braswell Dean, one of the leading supporters of the creationist movement in Atlanta, who has accused the organisation of defending the 'monkey mythology of Darwin'.

To Judge Dean — and other creationists — evolution is an "animal fairy tale", based largely on a "superstitious" trust in chance in its belief that random mutations could have produced the current diversity of animal types. "Scientific creationism is far more scientific and less religious" says

the Judge, who blames the teaching of "humanistic" values in schools for social problems from rising crime rates to abortion, pornography and pollution.

Not all creationists are as strident. But they do share a common belief that the teaching of evolution implies a relativity in social values that undermines both traditional codes of morality in general, and the authority of the Bible in particular.

So far the creationists have had little success in convincing the courts of their case. In most instances the barrier has been the constitutional requirement that the state should not teach religious principles. These were the grounds, for example, on which the courts declared as unconstitutional an 'equal time' bill passed in Tennessee in 1973.

Undaunted by such setbacks, creationists are now trying to get round this problem in two ways. Firstly they argue that, since it is impossible to produce scientific 'proof' of evolution, it is no more than a hypothesis which might otherwise be described as a faith or religion.

Secondly, the creationists seek to convince the legislators that creationism can be legitimately called a scientific theory. And they distinguish what is now called 'scientific' creationism from both 'divine' creationism (responsible for the failure of the Tennessee bill) and even from 'biblical' creationism (ridiculed in the Scopes trial).

To defend this position, scientifically-trained creationists now scan the scientific literature for uncertainties, ambiguities and potential errors in the ideas of conventional evolutionists.

Gaps in fossil records and uncertainties in dating techniques, for example, are used to weaken confidence in what is called the 'evolution model'. And where science has disproved rigid immutability by experiment, creationists will now allow 'adaptive mutations' — but still deny that one species can evolve into another.

Most scientists reply that weaknesses in a rigid interpretation of evolutionary theory do not undermine their general confidence in the principles involved; and they accuse creationists of distorting the scientific method, and cause-effect mechanisms of scientific explanation, into a form which few laboratory workers would recognise.

Creationists see it differently. "Negative evidence against evolution is the same as positive evidence for creation", says Dr Morris.

Whatever the philosophical disagreements, few deny that creationism has found a ready audience outside the scientific community. In particular school curricula remain a major battleground for the creationists and their opponents, largely because these are expected to demonstrate compatibility with community values.

A typical case is Cobb County, a suburb of Georgia. Last December biology courses were removed from high school graduation requirements in an attempt to resolve a conflict originating 18 months earlier when the local school board passed a resolution requiring evolution and creation to be given 'balanced treatment' in school courses.

Heated objections from science teachers and some community leaders led to eventual agreement that a voluntary course on 'comparative theories or origins' would be offered for high school students and that Darwinian evolution would not be included in any school biology course.

The Cobb County dispute is typical of conflicts now being fought out across the country. Most have in common the fact that, as Dr Dorothy Nelkin of Cornell University points out in her book *The Science Text-book Controversy*, the loudest critics of evolution are not from lower-class, uneducated backgrounds, but tend to be middle-class, technically-trained citizens.

Cobb County, an area of rapid post-war growth centred on the communications and aerospace industries, typifies what

Nelkin refers to as the 'paradox' that fundamental beliefs tend to flourish in those parts of the country which have recently become centres of high technology industries (for example Southern California and Texas).

Also typical of the Cobb County controversy is that it has taken place against sharp religious differences in the local community. Such differences have traditionally polarised around conflicting ways of interpreting the Bible. Indeed rather than a conflict between religion and science, the current disputes centre around the legitimacy of different forms of knowledge, whether used to support religious or scientific ideas.

In Atlanta, strong support for creationism has come from the more militantly conservative churches belonging to the Southern Baptist Convention, members of the currently dominant group within which is now the largest protestant sect in the US. In contrast, more moderate theologians are among the most persistent critics of biblical literalism, and have been

'Evolution is an animal fairy tale' — Judge Dean

among the most keen to keep creationism out of schools.

Further controversy has focused on the role of the Institute for Creation Research, (ICR) and was ignited when it was discovered that the 1978 resolution passed by the school board was almost identically worded to a model resolution circulated by the institute.

ICR is a division of the Christian Heritage College, a group which split from the more liberal American Scientific Affiliation in the 1950s largely over conflicting views on whether the Bible should be taken literally or metaphorically.

Since then, the institute has become a powerful centre for the teaching and propagation of creationist ideas which like other modern evangelical organisations, it has done with spirited fervour.

Institute members were also influential in setting up in 1963 the Creation Research Society, an organisation consisting of over 600 individuals with postgraduate degrees in scientific or technical subjects concerned with developing a 'scientific' critique of evolutionary theory — and arguing the case for a 'scientific' alternative.

Although denying any orchestration of local creationist movements, Dr Morris admits that an important role of ICR is to provide model resolutions and educational literature to groups prepared to support the contention that "teaching evolutionary theory alone is contrary to academic freedom, civil rights, and the freedom of religion".

Ironically much of the creationists' critique of the values implicit in evolutionary theory are similar to those coming from a very different perspective

which identify Darwin's ideas with the political norms of Victorian capitalism. But despite apparent similarities, the antagonisms are sharp.

Professor Richard Lewontin of Harvard University, for example, describes the recent rise of creationism as reflecting a "wave of anti-scientism", suggesting that its rejuvenation is "because intellectuals are identified as the allies of social movements" that challenge traditional power relations in society.

Conversely Dr Morris points out that many of the more politically radical evolutionists are among those questioning the more dogmatic aspects of Darwinian theory. But he castigates them for doing so "with prejudices tied to Karl Marx rather than Adam Smith".

It is difficult to judge the impact of the creationist movement. Some argue that, by causing publishers and teachers to drag their feet over introducing evolution into the class-room, creationists — in the words of one educator — "have had a tremendous impact on students in denying them access to scientific knowledge".

Others, however, are more prepared to be flexible. They use arguments from the sociology of knowledge to defend the interpretation of science as a belief system; and side with the creationists in their criticism of the more dogmatic assertions of some scientists and textbook writers.

Of greater concern to educationists are the implications of a movement which appears to attack abortion and homosexuality and defend the 'free world' with the same degree of dogmatism that it criticises in others.

Jeremy Rifkin, author of *The Emerging Order*, warns that what is now a religious movement, reacting in part to the 'idolatry' of scientific and technological truths, could turn into the opposite. "Christian doctrine, made an adjunct to right-wing and capitalist policies, could provide the necessary self-imposed order that a fascist movement in America would require to maintain control over the country during a period of long-range economic decline" he writes.

Creationists are used to responding in kind. Dr Morris argues that both fascism and communism have their roots in evolutionary thinking. He attacks the "humanistic and socialistic" biases of textbook publishers who refuse to mention scientific creationism. And he claims that creationist ideas have unfairly come under "bigoted pressure from the liberal news media".

Whatever the words used, the bitterness of the Georgia conflicts indicate that creationist ideology is unlikely to disappear. And it seems only a matter of time before some state requires creationism to be taught wherever Darwinism is invoked and another court is asked to rule on the respective definitions of science and religion. As Dr Mayer says, "It is all part and parcel of the signs of the times". □

Patenting nature's secrets and protecting microbiologists' interests

THE patenting of inventions in microbiology, is arousing unusual interest the United States and Europe. **Stephen Crespi**, Patents Controller at the UK National Research Development Corporation examines recent developments in Europe

THE US Supreme Court is hearing the appeal brought by Dr A Chakrabarty in 1972 over the rejection by the Patent Office of an attempt by GEC to patent an oil-consuming strain of *Pseudomonas* obtained through genetic manipulation. And in Europe, the European Patent Office has recently changed the mechanism, called Rule 28, for ensuring public availability to third parties of new strains of microorganism deposited in culture collections for patent purposes.

The legal controversy aroused in the US by the long-running Chakrabarty case has not fully erupted in Europe because there has been no comparable test case. But Europe must view developments in the US with interest because in a world in which legal systems borrow from one another the outcome in the US may affect that in Europe.

Some of the older American decisions show judicial condemnation of attempts to patent nature's secrets where living organisms are involved — although patents were allowed for meritorious discoveries of inanimate products of nature, vitamin B₁₂ being one of the most celebrated examples.

In Chakrabarty the fundamental point is simple; is a living organism which otherwise complies with legal requirements for patentability nevertheless disqualified because it is alive? In answering this question the court has to consider how to accommodate the product of genetic engineering in a patent system based on the models of classical physics and chemistry. However, if the decision of the Supreme Court later this year is limited to man-made organisms which are the result of genetic engineering it will be disappointing after so much effort has gone into dealing with the broader issue.

To put these developments into perspective it is worthwhile summarising the possible categories of patentable invention in microbiology. Microbiological processes have long been recognised by courts as suitable for process patents; and the newer patent statutes in Europe specifically refer to them. Patent claims may be presented for inventive developments of any of the methods of microbiology which serve a useful economic purpose such as improvements in culture media, culture conditions and the choice of strain used. Processes in which the sole novelty lies in the use of particular strains,

especially newly developed strains, have become conventional subjects of "process-of-use" patents.

Products produced by microorganisms such as antibiotics and enzymes have for a long time been patentable in the form of product claims where the products were novel and where the patent law of the country concerned permitted the so-called product-*per-se* claim, i.e. not limited in scope to a particular process. Where the product was not new, and novelty resided only in the process of making it, it was customary to use both process claims and also, where possible, the product-by-process claim, i.e. a claim to the product when made by the particular process. However, it is with the other type of possible product claim, the claim to the new strain of microbial cells themselves, that tension has arisen between applicants and examiners. Claiming the microbial biomass as a useful end product was generally acceptable but claims directed to the new strain *per se* seem more recently to have raised the kind of philosophical objections in the Chakrabarty case.

The traditional attitude of the UK patent system towards patent protection involving the use of living matter has been cautious but attentive to the needs of industry and applicants for patents. The following principles have operated: the concept of "manufacture" as essential for patentability; the fact that many living substances can be bought and sold like other commodities; giving the benefit of the doubt to an applicant where the law was uncertain but where the decision could be tested by a higher authority if any contestant so wished. The test of "manufacture" was whether the product was itself a manufacture or could be applied to manufacture, or whether the process was technical in nature as distinct from the establishment of conditions under which the organism was developed by essentially biological laws. Long before the subject attracted public comment, yeast manufacturers took out patents for new yeast strains, presumably because the alternative of trade secrecy was non-existent where the live microorganism was itself the item of commerce. British patents were also granted over the past twenty years for other new strains, cell lines, and attenuated viruses intended for vaccines. The *Fusarium graminearum* strains

intended as sources of single cell protein were patented without challenge in the UK in 1974 although held unpatentable in Eire and Australia by official ruling a few years later.

The British Patent Act of 1977 was brought in line with the European patent law of 1978 and practice should run in parallel under both systems. Recent informal discussions with EPO officials suggest that product-by-process claims to microorganisms will be accepted and that the decision on the patentability of unrestricted product claims to the strain *per se* will be taken soon. Much may depend on the circumstances of each case.

The number of patent applications on genetic engineering procedures reaching the publication stage is increasing. Once Patent Office Examiners have fathomed the extraordinary complexity of the subject there should be a spate of patents granted for techniques. It is difficult to see why recombinant DNA plasmids should be treated any differently from other chemical substances but whether claims to plasmids and transformed strains are obtained remains to be seen. What commercial value do these claims have and can they be policed inside the competitor's factory gates? We cannot yet judge the value of these to the innovators especially with so little experience of their usefulness. Therefore instead of being negative or restrictive we should explore ways in which the patent law can encourage these new areas of research.

What is the objection to patenting living matter? Some condemn it by asking where it will end and they argue that a logical extension to higher life forms supports their view. But law and logic are not identical and this argument has to overcome two objections.

The first is that one class of higher life forms is already protected, namely plants by the plant patents in the US and plant breeders' rights elsewhere. The latter are distinct from patent protection and show an interesting difference: the plant breeder can control not only the commercial marketing of the reproductive material of the new variety but also its subsequent multiplication whereas normally once a patentee has sold the product covered by the patent he cannot control it further. Secondly, patent legislation in some countries (including that of the European Patent Convention) specifically excludes patents for plant and animal varieties.

The patent law exists to benefit research and its financial supporters. If it becomes necessary to draw an arbitrary line between what living organisms are or are not patentable it is within the wisdom of judges

and administrators of the law to do so in a way which supports technology and is generous to the inventor without harm to anyone else. Borderline cases will arise where the meaning of the terms 'plant' and 'animal' will have to be looked at closely but the constraints against patents for higher life forms are clearly built in to the present laws, at least according to the European model.

In presenting their survey of the patent law to the Supreme Court, the US judges of the lower court have approached the question on the pragmatic ground of usefulness to industry where they see no distinction between living microorganisms and chemical elements and compounds. If it is socially acceptable and desirable for pharmaceutical companies to develop new microorganisms and produce products containing living material such as "live" virus vaccines there can be no reason for restricting the patent cover available for these innovations.

To erect obstacles to patent protection is to encourage the secrecy which the patent law is designed to discourage. The patent system has in recent years become much more open especially with its emphasis on early compulsory publication of patent applications which in the past often remained confidential in the Patent Office for a long time. However, the emphasis on early publication has caused problems for microbiologists because a new strain of a microorganism must be available to third parties at the same time as publication. The European Patent Convention of 1973 set the trend on this point.

One of its regulations, Rule 28, had said that a new strain must be deposited in a culture collection before a European patent application could be filed properly and also insisted on the accessibility of the strain to others, subject to a few conditions, on publication of the application 18 months or so after the priority date. This contrasted with US and Japanese patent law where release of the strain is obligatory only when an enforceable right is obtained.

However, the European Patent Office has recently modified Rule 28. Availability of the strain to third parties can now be restricted between first publication of the application and the eventual grant of patent rights. During this time the applicant will be able to limit access to the strain to an independent expert acting on behalf of third parties but bound by certain conditions including that of not passing the strain out of his hands.

This improvement of the rule concludes over six years of effort by European industry and others to persuade the authorities that unrestricted availability of the culture before any rights are granted involves loss of control at too early a stage. This has been one of the first controversial questions tackled and solved by the EPO since it began operation in June 1978. The decision to change the rule has anticipated

Evolving ideas

EVOLUTION is not really in trouble, of course, it has never been healthier. It has gone into the computers. This is a sad business when one thinks of the halcyon days about a century ago. It is true that Darwin, the brooding sage, was a recluse at Down, but his supporters were having a wonderful time. We have been reminded of this in the splendid television series "The Voyage of the Beagle", and especially by the exciting re-enactment, on this programme, of the confrontation between Bishop Wilberforce and Thomas Huxley. The question asked by the Bishop was on which side Huxley claimed descent from the apes. Today we might reply that the maternal line of inheritance has a slight edge because mitochondria probably travel with ova. However, Huxley's thunderous response was directed personally at Wilberforce, whereupon it is said, a young woman fainted. Ironically, Queen Victoria, the supreme head of Wilberforce's church, carried a mutant gene for one of the blood-clotting globulins (Factor VIII), for the male haemophiliacs among her descendants provided a tragic and classic example of the ruthless effects of natural selection.

Evolution then set forth for many years on an adventure among fossils of extinct animals and plants. Pterodactyl, *Tyrannosaurus* and *Archaeopteryx* became household words. Descriptions of the bones of our ancestors were often in the news. The Scopes trial put evolution into the field of entertainment. Next, biochemists devised methods for determining the sequences of amino acids in proteins. It became possible to measure evolutionary divergence numerically in terms of amino acid differences between similar proteins in various species. Haemoglobins of gorillas, chimpanzees and human beings were distressingly similar, but widening differences were found in other species. The fun was disappearing from evolution, but worse was to come for the classical taxonomists. Incredibly rapid new methods were perfected for measuring long sequences of nucleotides in DNA, and the results, photoreduced to near-illegibility, appear in *Nature* almost every week.

A few years ago, we could examine

the UK report on biotechnology published last week (see *Nature*, 10 April, page 502) which strongly criticised the lack of protection under Rule 28.

Rule 28 was also updated to conform to the corresponding rule in the Budapest Convention of 1977 which provides that deposition of the strain in a single officially recognised culture collection will suffice for the individual, national procedures.

The detailed application of the independent expert idea remains to be

THOMAS H. JUKES

phenotypes but we never expected to be able to read genes. Now every sequencer can become a computer-aided evolutionist. Viruses evolve just like entire organisms; in fact, genes in simian virus 40 and the polyoma virus have diverged even further from each other than genes for the alpha and beta chains of haemoglobin, which have spread far apart in the 500 million years since they separated from a common ancestral molecule. But who knows how fast viruses evolve? They leave no fossilized imprints in the rocks as guideposts of their age.

To look for a gene in DNA, you scan for "open reading frames". These are regions in nucleotide sequences that are free from occurrences of TAA, TAG and TGA: the "stop signals" in protein synthesis. It is becoming quicker to find new proteins in DNA sequences than to separate them from protoplasm. It is even possible to find genes that are no longer in use. Phil Leder recently called such a gene (for a mouse alpha haemoglobin chain) a "rusting hulk", because it had accumulated so many changes, including deletions and insertions.

All evolutionary changes result from inherited changes in DNA molecules. It is difficult to get emotional about alterations in the linear arrangement of A, C, G and T. The spiritual descendants of Bishop Wilberforce must find it rather dull to argue with computer programs.

worked out but the intention is that the expert will carry out experiments on behalf of third parties and potential opposers of the patent to test the patent disclosure and make an evaluation of the invention. The expert will be chosen by agreement between the applicant and the party requesting the strain or from an official list of recognised experts. Consequently the services of eminent microbiologists will be in demand and experts who might be willing to undertake this role are being canvassed. □

CORRESPONDENCE

Nuclear technology is not the threat

SIR,—Mr A. B. Lovins' article (28 February, page 817) confines itself almost entirely to a discussion of the use of reactor grade plutonium in the construction of bombs, either by terrorist groups, or by governments. I do not believe myself to be enough of an expert on these esoteric branches of industrial chemistry and nuclear physics to comment usefully on the technical aspects of the article, and in any case I would prefer to concentrate on some implicit non-technicalities.

First, there is the claim, not made here by Mr Lovins, that the increased availability of dangerous materials will increase the risk of their misuse. While there is some truth in this depressing doctrine, I feel that the size of such risks is dominated by the proportion of people who are keen to use terrorist methods, rather than by the technology of their particular community.

No, the question surely is whether we are to give up clean, reliable, safe, economical and enormously useful techniques simply for fear of what the malevolent may do. If we are, where does this line of argument stop? Do the Friends of the Earth want us to give up aviation, liquid natural gas, or genetic engineering? And if not, why not? Or, to put it another way, should Adam have stopped Eve from eating that Fruit?

In addition, I have some specific quarrels with Mr Lovins' article. Who, for instance, were the "three high-technology nations" whose ministers were so misled? Again, no-one associated with the anti-nuclear movement is entitled to complain about "lost, oversimplified or garbled" advice. And what on Earth does he mean by saying that "the implication that the effects of even a crude, minimal 0.1-1 kton explosion would be tolerable for a free society is at best disingenuous"? Non-free societies are entitled to proceed, apparently.

Without making any statement about the possible carnage in such an explosion, I would like to point out that conventional accidents sometimes take thousands of lives in free societies, and presumably in non-free ones too. The multiple standards of response to such disasters is sadly but glaringly highlighted by the failure of the Morbi dam in Gujrat State, India, in August. It seems to have taken some hundreds of lives at least, and passed almost unnoticed in the Year of Three Mile Island.

Yours faithfully,

J. F. CRAWFORD

Klein Doettingen,
Switzerland.

Comparing the diets of laboratory animals

SIR,—It has been demonstrated several times that toxicological experiments performed in different laboratories are liable to unexplained variations in result. Amongst the possible reasons for this observation, are differences in diet of the experimental animals (see for example Hathcock and Coon *Nutrition and Drug Interrelations*, Academic Press, New York 1978). Of 89 randomly-chosen recent publications in the fields of oncology, pharmacology and toxicology, more than half failed to specify the diet fed to their laboratory rodents. Often considerable portions of the 'methods' section were description of the animals, sources of

chemicals used, etc, but the nearest any of the authors got to specifying their diets was to give the manufacturer's name. This implies that the authors consider stock diets to be standard. However, my survey of 24 UK stock diets for mice and rats has shown that for each nutrient, very large differences in the diet composition exist. Amongst nine minerals, the coefficient of variation ranged from 16% to 80%, with a median value of 28%. Similarly for 12 vitamins, the range was from 20% to 91%, with a median of 62%.

The survey was based on the best information available, but in all cases it is a calculated figure only, based on the ingredients of the diets. Only one British manufacturer has been prepared to supply details for one diet of average analyses after production. Some manufacturers at extra cost will provide analytical details to customers on a batch basis, and it is these figures that are required for a scientific evaluation of diets on a comparative basis. The majority of nutritionists use semi-synthetic diets, rather than stock diets, and it is perhaps for this reason that their attention has not been focused on diets used by non-nutritionists and why so little nutritional work has been done in this field.

It is the intention of the Laboratory Animals Centre to try to obtain information about actual analyses, for nutrients and contaminants, on stock diets worldwide. It would then be possible to help those who are trying to explain differences in results between similar experiments in different laboratories, in which it is suspected that dietary variation might have been important. In the furtherance of this aim, it is suggested that diet manufacturers and scientists who have relevant analytical data should contact the Laboratory Animals Centre to discuss the possibility of collaboration in such a study.

Yours faithfully,

A. WISE

Carshalton, Surrey, UK

Establishing the case for the Maunder Minimum

SIR,—The News and Views contribution of 31 January (page 427) entitled "Was there a Maunder Minimum?" projects a superficial understanding of the meticulous work by solar astronomers, historians, climatologists, palaeobiologists, and scientists from a host of other research disciplines supporting a marked diminution in solar activity during the 17th century.

Table 1 of the article shows that there were nine naked eye sunspot records during the decade beginning 1610, six in the 1620s, nine in 1639, two in the 1640s, three in the 1650s, one in the subsequent decade, then none, and finally one in the 1680s. Taken at face value, the new *fang chih* records would seem to lend support to a dramatic reduction from about 1640 in the number of sunspot groups or individual spots large enough to be seen by the naked eye under suitable atmospheric conditions. But a direct interpretation of such limited data is superficial. As your article stresses, the *fang chih* do not present an unbiased sample of data, any more so than the records in the official dynastic histories. At least for the latter one has some check on completeness of the data by looking at the continuity of official records of other astronomical phenomena. However, because

of political, social and astrological influences, oriental sunspot records are by themselves of little value; as previous investigators have been careful to stress, they provide at best merely circumstantial evidence for excursions in solar activity. There is no point arguing for or against a Maunder Minimum on the appearance or absence of naked-eye sunspot records from the orient when post-telescopic (1610) occidental records, free from political-astrological influences, are available and when a wealth of other indicators of solar variability have been investigated. Yet none of these are mentioned, the reality of the Maunder Minimum being called into question on the basis of a few provincial oriental records of doubtful reliability.

The leading late 17th century observational astronomers lamented the scarcity of sunspot activity. Here we have more than just a chance mention of detections, but professional observers insisting that it had been a decade or more since any spots had been seen. Spots there certainly were during the Maunder Minimum (1645-1715) but greatly reduced in frequency and extent. Thus, for example, Stephen Gray noted in 1705 "the Sun was much more productive of (spots) in (Galileo's) time than it has yet been in ours, and the Regions Producing them had a far Greater extent". However, if one was hesitant to accept the direct evidence of contemporary scientific writings, indirect indicators provide near-conclusive proof of reduced solar activity. A history of the flux of cosmic rays, related to solar activity (and hence to sunspot occurrence) can be constructed from isotopic anomalies preserved in tree rings and ice cores. All such investigations reinforce the case for the Maunder Minimum.

Lead petrol additives

SIR,—In an otherwise valuable contribution to the debate on the health impacts of childhood lead exposure, M.R. Moore (24 January, page 334) may have unnecessarily compromised the case against leaded petrol by conceding significant economic benefits.

It has long been accepted that lead petrol additives are a major contributor to combustion chamber deposits responsible for increased octane rating demand. Measurements of this effect (e.g. G. Cornetti *et al*, *The Journal of Automotive Engineering*, June 1971, 8-14) have demonstrated fuel efficiency penalties that are greater than the gains made possible by increased compression ratios with high octane, leaded petrol.

Yours faithfully,

NEWS AND VIEWS

Interferons and the immune system

from Barry R. Bloom

The current exuberance about interferon reflected in these pages referring to interferon as "potentially the wonder drug of the 80's" recalls the comment of Michael Faraday on being questioned sceptically by Gladstone on the uses of his research on electromagnetism, "One day, it will give rise to a great industry upon which you can levy taxes." Why such enthusiasm? At least part of the answer lies in the recent appreciation of the regulatory effects that interferons exert on the immune system.

Interferon has been defined by its antiviral effect and has been considered almost exclusively as a potential antiviral agent. (The work of Gresser on the other biological effects of interferons stands as an heroic exception (*Cell. Immun.* **34**, 406; 1977).) Yet evidence for its efficacy in acute virus infections has been relatively disappointing until recently although it does seem a promising treatment in hepatitis, rabies, varicella zoster, herpes keratitis and rhinovirus (common cold) infections. But the most significant boost to the budding interferon industry comes from trials of interferon in cancer patients, initially stimulated by the studies of Strander and his colleagues on osteosarcomas, and reinforced by preliminary findings in non-Hodgkins lymphomas, breast cancer and multiple myeloma. So far, however, the optimism is based on published results in fewer than 50 patients in trials that have not been randomized, blinded or well controlled. As more and cheaper interferon becomes available, larger trials will be carried out.

The principal approach to studying both

the antiviral and antitumour effects of interferon has been to look at the direct effects of interferon on appropriate tumours or virus-infected target cells. Various metabolic pathways activated by interferon have been elucidated, involving 2' 5'-polyadenylate synthetase, protein kinase and nucleases which may play a part in blocking initiation of viral or host protein synthesis and in breakdown of viral and host mRNAs (see *Nature* **282**, 364; 1979). One probable consequence of these regulatory changes is a relatively general inhibition of replication of various normal and neoplastic cells. *In vivo* experiments confirm that interferons inhibit tumour growth in several animal models, but they can also suppress liver regeneration in partially hepatectomized mice and even inhibit growth and development of suckling mice.

In the light of the general growth inhibitory effects of interferons, it is not surprising that the first effects of interferon on the immune system to be studied were its immunosuppressive activities. Several laboratories showed that interferons can inhibit antibody formation to thymus-dependent (sheep erythrocytes) and thymus-independent antigens *in vivo* and *in vitro*. In this regard type II 'immune' interferon (produced by T cells) has been found to be 10-100 times more suppressive than type I interferon (the type produced by leukocytes and fibroblasts) (Sonnenfeld *et al. Cell. Immun.* **34**, 193; 1977). Interferons suppress mitogenic responses of both T cells and B cells *in vitro*. Indeed, interferons seem to be responsible for mediating the suppression of the concanavalin A-activated human T suppressor cell (Kadish *et al. J. exp. Med.* in the press). In most studies *in vivo*,

relatively large amounts of crude interferons have been used, and while suppressive effects were observed, interferon can hardly be regarded as one of the more potent immunosuppressive agents available. Indeed, little evidence for suppression, of antibody formation at least, has been seen in patients receiving interferon therapy for cancer or virus infection. Although interferon suppresses graft-versus-host reactions in animals, its usefulness in human bone marrow grafts is limited because its growth-inhibitory activity has blocked bone marrow proliferation and reconstitution. Thus the balance between useful immunosuppression, and unacceptable side effects may be delicate.

Interferon and NK cells

In 1975 it was first recognized that normal spleen cells of some strains of mice were cytotoxic *in vitro* selectively for neoplastically transformed cells (Kieślinski *et al. Eur. J. Immunol.* **5**, 112; 1975). The cells responsible for this spontaneous cytotoxicity were termed 'natural killer' (NK) cells and are quite distinct from conventional B cells, T cells or macrophages (*Transpl. Rev.* **44**, 1979; *Natural Cell-Mediated Immunity against Tumours* (ed. Herberman) Academic Press, in the press). Athymic nude mice spleens possess increased NK activity, whereas cells from individuals with Chediak-Higashi syndrome or its murine analogue, *beige* mice, are almost totally deficient. The provenance and fate of NK cells remain unknown. NK cells bear surface markers characteristic of the T-cell lineage (Minato *et al. Ann. N. Y. Acad. Sci.* in the press), but also seem to share characteristics in common with

Barry R. Bloom is Professor and Chairman in the Department of Microbiology and Immunology at the Albert Einstein College of Medicine of Yeshiva University, New York.

macrophages (Lohmann-Matthes *et al. J. Immun.* **123**, 1883; 1979). Alternatively, they may represent an independent lymphocyte pathway. It may well be that NK activity is mediated by more than one cell type in different systems.

Interferon seems to be the key immunoregulatory signal for NK activity. Several independent studies earlier suggested that inducers of interferon *in vivo* such as poly(I):poly(C) or tilerone augmented NK activity in spleen cells (Gidlund *et al. Nature* **273**, 759; 1978; Djeu *et al. J. Immun.* **122**, 175; 1979). Surprisingly, known immunological adjuvants such as BCG or *Corynebacterium parvum*, which in some models have been shown to enhance resistance to tumours in both conventional and athymic mice also augment NK reactivity (Wolfe *et al. Nature* **252**, 584; 1976). It has now formally been established that interferon, including chemically-purified material, can markedly augment cytotoxicity of NK cells for appropriate target cells (Trinchieri *et al. J. exp. Med.* **147**, 1314; 1978; Zarling *et al. J. Immun.* **123**, 63; 1979; Minato *et al. op. cit.*).

Lymphoid cells are not only regulated by interferons but actively produce them. Type II or 'immune' interferon is produced by mitogen or antigen-stimulated T cells (Epstein in *Interferons and their Actions* (ed. Stewart) 91, CRC Press, Cleveland, 1978). Interaction of a non-B, non-T cell population of human peripheral blood cells with a majority of human tumour cell lines tested *in vitro* resulted in the production of type I leukocyte interferon, and there seemed to be a general correlation between the susceptibility of tumour cells to lysis by NK cells and the tumour cells' ability to induce interferon production by NK cells (Trinchieri *et al. J. exp. Med.* **147**, 1299; 1978). Several laboratories have shown that NK cells bind to appropriate target cells, and have used specific adsorption to targets to enrich for human NK cells and examine their morphology and characteristics (Timonen *et al. Cell. Immun.* **48**, 133; 1979; Roder *et al. J. Immun.* **121**, 2509; 1978; Jensen & Koren *J. Immun.* **123**, 1127; 1979). After the binding of a relatively homogeneous population of medium-large lymphocytes with striking cytoplasmic granules to susceptible target cells, these bound presumed NK cells rapidly become immunofluorescence-positive for interferon (Saksela *et al. Annl. N. Y. Acad. Sci.* in the press). While it has not formally been established that the interferon-producing cells are the cytolytic ones, the correlation between binding, interferon-positive immunofluorescence and cytotoxicity for the targets is striking.

Interferon could augment NK activity in two ways. (1) It might activate existing NK cells, like the activation of macrophages by lymphokines, or (2) it could trigger the differentiation of a precursor to the NK cell into an effector cell. It has recently been

shown in nude mice that both NK cells and interferon-producing cells are susceptible to anti-Ly 5 antibodies (Cantor *et al. Immun. Rev.* **44**, 3; 1979) and anti-Qa 5 antibodies (Chun *et al. J. exp. Med.* **149**, 426; 1979). When NK activity was depleted by treatment with anti-Ly 5 + complement, interferon restored it within 3 h, and the induced effector cells expressed the Ly 5 surface marker (Minato *et al. op. cit.*). In contrast, treatment with anti-Qa 5 + complement eliminated NK activity which could not be restored by addition of interferon, and hence serves as a marker for the NK precursor. Precisely analogous results were found using human cells depleted of functional NK activity by selective adsorption to target cells which could be induced to become cytolytic after interferon treatment (Saksela *et al. Scand. J. Immun.* **10**, 257; 1979). Thus activation of NK cells by virus or appropriate tumour cells initiates a positive feedback circuit mediated by interferon resulting in rapid differentiation and amplification of NK function.

Role of NK cells in resistance to tumours

What is the evidence that interferon-induced NK cells have any significant immunological role *in vivo*? The mechanism by which interferon exerts antiviral effects *in vivo* should be re-examined following recent experiments which show that although human interferon did not protect monkey cells against vaccinia virus infection *in vitro*, treatment of monkeys themselves with interferon effectively prevented the growth of locally inoculated vaccinia virus (Schellekens *et al. Nature* **278**, 742; 1979). These results strongly indicate that in this, and perhaps other systems, interferon may exert its protective effects not by acting directly on target cells but perhaps through its effects on the immune system. There is evidence for a significant role of interferon in natural resistance to acute infections (Gresser *et al. J. exp. Med.* **144**, 1305; 1976). Surprisingly, the interferon-NK cell system may be far more important in resistance to persistent virus infections and tumour cells.

As few as 10–100 HeLa or BHK cells produce tumours in all athymic *nude* mice; yet 10^6 – 10^7 of the same cells persistently infected with any of six RNA viruses fail to grow as tumours (Minato *et al. J. exp. Med.* **149**, 1117; 1979). The persistently-infected tumour cells were killed by NK cells *in vitro*, whereas the uninfected parental tumour cells were not. One variant of BHK cells persistently infected with VSV was an excellent inducer of interferon and capable *in vivo* of augmenting cytotoxicity to irrelevant target cells, but was itself resistant to NK killing *in vitro*. This variant formed disseminated tumours and metastases in *nude* mice.

Important evidence for a role for NK cells in restriction of metastases has

recently been provided by remarkable experiments in which a variant of the B16 murine melanoma tumour line which is susceptible to killing by NK cells *in vitro* showed enhanced growth, faster induction time and markedly increased metastatic capability in *beige* mice, which are deficient in NK cells, compared with control mice (Talmadge *et al.* this issue of *Nature*, page 622; see also Karre *et al.* this issue of *Nature*, page 624, on the possible role of NK cells in resistance to syngeneic leukaemias in mice). Talmadge *et al.* find that induction of interferon by infection with LCM virus decreased the tumour growth rate and metastatic frequency even in *beige* mice. Treatment of *nude* mice, which ordinarily reject tumour cells persistently infected with virus, with antibodies to mouse interferon not only results in the growth of the tumours, but in their generalized metastasis (Reid, *et al. 3rd Intl Workshop on Nude Mice* in the press).

Much less is known about the role of the interferon-NK system in human disease. In diseases possibly caused by persistent viruses such as multiple sclerosis and lupus erythematosus, diminished production of leukocyte interferon and NK activity *in vitro* by peripheral lymphocytes in some patients suggest that such deficiencies could predispose to persistent virus infection (Minato *et al. op. cit.*). Several investigators are finding diminished NK activity in patients with tumours (Hersey *et al. Brit. J. Cancer* **40**, 113; 1979; Pross & Baines in *Natural Cell-Mediated Immunity against Tumours* (ed. Herberman) Academic Press, in the press). Diminished NK activity was found in familial melanoma patients and their relatives suggesting that the deficiencies in these patients may be a predisposing factor to their disease, rather than simply the result of disseminated metastases.

Questions for the future

The direct biological activity and immunoregulatory activity of interferon has raised high expectations and many questions. Yet, there are very few cases in which it has been possible to disentangle the direct effects of interferons *in vivo* on tumour cells and target cells for viruses from their effects on the immune system, and this will probably require analysis of the genetic make-up of peculiar mouse strains, for example *beige* and *nude* mice.

If a positive feedback circuit regulates the differentiation of NK cells and precursors, are there factors which normally restrict or regulate this process? One wonders particularly whether T cells, or a subset, intervene to restrict the development of NK cells. Do leukocyte and 'immune' interferons have any unique functions or target activities?

Are NK cells clonal, and do they have specificity in the immunological sense, or merely selectivity? If the latter, what are the common surface determinants which they recognize in various tumour and virus-

infected cells; if the former, can these cells be cloned and specifically amplified *in vitro*?

Is the role of interferon in natural resistance to infection or tumour spread primarily local? Can systemic administration provide an adequate effect on regional responses?

Does a deficiency either in interferon production or NK activity predispose to persistent virus infections or metastases, and can *in vitro* tests of these parameters be used as diagnostic adjuncts? In patients with these diseases does interferon augment NK activity in some patients and not others, and if so, can prescreening of patients scheduled for interferon therapy for *in vitro* sensitivity to interferon identify those showing better clinical response *in vivo*? Answers to many of these questions

are bound to influence a great deal more than the prosperity of the interferon industry.

In understanding immunological effects of interferon, it is important to note that there are very few immunology laboratories that are able to produce and purify the various types of interferon and at the same time pursue their effects on the immune system. For rapid progress, immunologists will be dependent on the good will and collaboration of the interferon experts providing them with purified material for these studies.

At a minimum, one may hope that the immunologists could repay them both by producing monoclonal antibodies against various interferons and providing insights into the mechanisms by which their product exerts its effect. □

abundance of interstellar H_2O can be deduced. Here is where the new line discovered by Waters *et al.* comes in. In the Orion molecular cloud where the new line is seen, lines of most other molecules have a characteristic emission profile (a sharp spike superimposed upon a broad pedestal) indicative of rapid mass motions within a small energetic core surrounded by a larger more quiescent region. Molecules known to be masering in Orion (OH, 22 GHz H_2O , CH_3OH) do not show this profile, but non-masering molecules do. Although they are unable to resolve the emission region spatially with their 91 cm telescope, Waters *et al.* find that the 183 GHz water emission emulates quite well the spike-plateau profile of other molecules, and therefore conclude that this water transition is reasonably normally excited. This spike feature apparently arises in the quiescent region whose size (about 4 arc min) and temperature (about 80 K) are well determined from the lines of many other molecules. If the 183 GHz line of H_2O is thermalized at this temperature, Waters *et al.* estimate the H_2O abundance at a few times 10^{17} cm^{-2} . If one calculates the excitation produced by known infrared radiation fields and by collisions with other molecules, then H_2O abundances as large as 10^{18} cm^{-2} can result. The net abundance uncertainty (a factor of 10) is in fact no greater than applies to many other molecular species observed from the ground, and will be greatly reduced by use of a larger airborne telescope which resolves the source. This first result already yields important ratios for the interstellar chemist: the fractional abundance of H_2O is about 10^{-6} , consistent with ion-molecule chemical models. From ground-based studies of HDO, one deduces that $\text{HDO}/\text{H}_2\text{O} \gg \text{D}/\text{H}$, showing that water, like several other interstellar molecules, concentrates deuterium with great efficiency.

Even more recent detections of hitherto inaccessible interstellar lines and molecules have been made from above the troposphere by T. L. Phillips and colleagues, using the KAO (IAU Symposium 87, Mt. Tremblant, Quebec, August 1979). The $4_{14-3_{21}}$ transition of H_2O at 380 GHz has a spectral profile in the Orion source similar to that of the 183 GHz line, and thus is consistent with the picture discussed by Waters *et al.* Carbon monoxide, the most important tracer of the dense molecular interstellar gas, is now much better understood thanks to the detections in mid-1979 of the $J=3-2$ and $4-3$ transitions at 345 and 461 GHz respectively. These higher-lying CO transitions often exhibit marked self-reversals in their profiles, which are usually not evident in the lower-lying lines previously studied from the ground, and which are indicative of complex temperature, velocity, and density variations within the clouds. Such self-reversals may also bear on the classical

Interstellar spectroscopy

from B.E. Turner

ALMOST a dozen years ago the first interstellar polyatomic molecules were detected by ground-based radio astronomy in the microwave region. Today, the list of known interstellar molecules stands at 53 and includes 90 different isotopically substituted species. These molecules have provided a new and unique tool for studying the dense, cool component of the interstellar medium, a component now recognized as comprising half of the interstellar medium by mass. Molecular clouds which range up to 10^7 solar masses are the sites of star formation throughout the Galaxy and have an important, if not dominant, effect on the dynamics and kinematics of both the interstellar medium and of the stellar populations immersed in it.

Both the physical conditions in these interstellar clouds, and their chemistry, have been subjects of intense study over the past decade. The molecular species identified range in complexity from 2 to 11 atoms. Not surprisingly, the more complex the molecule, the more speculative our understanding about how it is formed. Thus, meaningful tests of the current theories about chemical processes in interstellar molecular clouds necessarily involve the simpler of the known species. To be useful either as tests of chemical models or as probes of physical conditions, these simple species must have reliably determined abundances.

Adequate study of important interstellar molecules is hampered or prevented by the Earth's atmosphere as it absorbs strongly in several bands of O_2 and H_2O at wavelengths longer than 800 μm , and fairly continuously in a myriad of water transitions over the entire sub-millimetre region below 800 μm . The most important

interstellar molecules are light, and have many important transitions in the sub-millimetre region, observations of which are needed to determine abundances. Among these are CO and HD, which along with atomic carbon provide the principal cooling transitions of dense clouds. Also included are all of the basic hydrides of the hydrocarbon, nitride, and hydroxyl families and of a number of elements (Mg, P, Na, Cl, Al, Ca, Fe) not yet identified in interstellar molecules. Key transitions of interstellar species such as H_2O and O_2 are of course absorbed by the corresponding telluric lines.

In the past few years a strong effort has been mounted to study extraterrestrial lines from above the troposphere. These studies conducted with the Kuiper Airborne Observatory (operated by NASA Ames Research Center) have begun to pay handsome returns with the airborne detections of the important interstellar line of H_2O at 183 GHz, two sub-millimetre lines of CO and one of H_2O , and, very recently, the 492 GHz fine-structure transition of atomic carbon.

In a series of observations from the KAO beginning in late 1976 J. W. Waters and colleagues (*Astrophys. J.* **235**, 57; 1980) made the first detection of an interstellar molecular line inaccessible from the ground, the $3_{13-2_{20}}$ transition of H_2O at 183 GHz. Interstellar H_2O has long been observed from the ground via its $6_{16-5_{23}}$ transition at 22.2 GHz. In normally excited H_2O such as occurs in the Earth's atmosphere, the 22 GHz line is very weak, thus explaining the modest (a few percent) absorption by the atmosphere here. By contrast, the interstellar version of this line is far from normal — it is observed without exception as a powerful maser whose pumping mechanism is not yet understood so that little information about the

B.E. Turner is at the National Radio Observatory, Charlottesville, Virginia.

question of whether molecular clouds collapse, and at what rate, a question of direct consequence to the puzzle of how stars form from such clouds. Late last year Philips and his colleagues made perhaps the most important discovery yet from the KAO, the fine-structure (3P_1 - 3P_0) ground-state transition of neutral atomic carbon at 492 GHz (BAAS 11, 686; 1979). The line is apparently observable everywhere that CO is seen. Not only is carbon chemistry predominant in interstellar molecular clouds, but models predict extremely abrupt transitions in the ionized, neutral, and molecular forms of carbon as a function of optical depth of the cloud. Such predictions can now be checked. Neutral atomic carbon is also expected to be one of the major coolants of clouds by emission in its two fine structure transitions. A much better determination of heating-cooling mechanisms in these clouds is now possible. It is quite probable

that the new carbon line will take its place along with the atomic hydrogen line at 21 cm and the CO line at 2.6 mm as one of the three most important interstellar lines in the radio-infrared spectrum.

In the short time that observations of the interstellar medium from above the troposphere have been possible, the results have been quite remarkable. More of the same can be expected. Yet to come are searches for the hydrides of many elements, the other fine structure transition of carbon (at 812 GHz), important molecules such as HD and O_2 , and vibrationally excited molecular species of all kinds including several (such as acetylene and carbon dioxide) that because of their symmetry do not radiate at microwave frequencies. The KAO has been the vital first step in opening one of the last, and potentially richest, regions of the astronomical spectrum — that of the sub-millimetre and far infrared. □

Spinning yarns about plant cells

from Clive Lloyd

WHERE and how is cellulose made? With rare exception it doesn't seem to be made inside plant cells, neither does it appear to be spun-out from precursors away from the cell membrane. In fact, it has long been held that cellulose is synthesized at the plasma membrane but although convincing images exist of the sites of assembly in algae there is still little agreement about the nature of the synthesizing machinery in higher plants. Membrane fractions will add radioactive glucose (from nucleotide-glucose) to primer whereas unbroken protoplasts will not and so it is thought that the activated glucose must be donated to membrane-located cellulose synthetases at their cytoplasmic face. Splitting the lipid layer open by freeze-etch/freezefracture techniques should reveal any large transmembranous assemblies but it is precisely this area of producing artefact-free images of putative "assemblyases" which is fraught with problems and has prolonged the debate about what happens in higher plants.

It was in 1963 that Preston suggested the existence of enzyme particle complexes in the plasma membrane responsible for the synthesis of cellulose microfibrils and they were soon found by the new technique of freeze-etch/freezefracture (see Preston *The Physical Biology of Plant Cell Walls*, Chapman & Hall, 1974). With the algae *Oocystis* (Brown & Montezinos *Proc. natn. Acad. Sci. U.S.A.* 73, 143; 1976) and *Glaucozystis* (Willison & Brown *J. Cell Biol.* 78, 103; 1978) and the bacterium *Acetobacter xylinum* (Brown, Willison & Richardson *Proc. natn. Acad. Sci. U.S.A.* 73, 4565; 1976), intramembranous com-

Fig. 1 A model demonstrating the proposed relationship of terminal complexes and rosettes in association with the plasma membrane. The membrane, microfibrils, and microfibril-associated structures are drawn approximately to equivalent scale. The dimensions of the rosettes (C), the terminal complex (A and B) and the microfibril (MF) are derived from freeze-fracture images. (from Mueller & Brown, *op. cit.*)

plexes revealed by this technique pack together in lines and are associated with cellulose microfibrils on the external face. Linear (as well as hexagonal) arrays of particles are also seen in fractured membranes of regenerating protoplasts from the higher plant *Skimmia japonica* (Robenek & Peveling *Planta* 136, 135; 1977) when glycerol is used. However, Davey and Mathias (*Protoplasma* 100, 85; 1979) have shown that the formation of both hexagonal and linear arrays of membrane particles can be attributed to the use of glycerol — a cryoprotectant known to induce similar artefacts in animal cells. So, do intramembranous assemblies participate in processing the higher plant cell wall or do they not? They do according to work from R.M. Brown's laboratory. In 1976, Mueller, Scott and Brown (*Science* 194, 949) presented pictures of the extracellular face of fractured membranes from untreated corn roots, showing globular complexes attached to the ends of nascent cellulose microfibrils. Willison and

Grout (*Planta* 140, 57; 1978) also avoided chemical fixation or glycerol treatment and showed similar globules attached to the ends of microfibrils in radish roots. Tomato and tobacco protoplasts were also studied but even though they were presumably regenerating a wall, no impressions of wall microfibrils were made into the membrane, thus preventing any correlation between cellulose microfibrils and the intramembranous particles. Without their walls, protoplasts are fragile and are prevented from swelling and bursting by regulating the osmotic concentration of the suspension medium with sugars. It seems likely, then, that in contrast to whole tissue, a wall in the process of being regenerated by a protoplast may be physically incapable of imprinting its image through to the membrane's fracture-plane where the particles are seen. For several reasons, therefore, it would seem that protoplasts may not be ideal for studying wall synthesis and now Wilkinson and Northcote (*J. Cell Science*, in the press) reinforce the message by reporting that even plasmolysis (a routine preliminary to preparing protoplasts from suspension cells) induces proteins to crystallize in the plane of the membrane as the area of surrounding lipid bilayer is reduced during retraction of the protoplast from the cell wall. It would seem that particle arrays produced by any treatment (not just glycerination) which causes plasmolysis could be artefactual.

This readiness of intramembranous particles to pack together under varied experimental conditions tends to sap confidence in the physiological relevance of ordered particle arrays to cellulose biosynthesis. It is satisfying therefore to find further good evidence in higher plant cells which favours the idea that specialized particle rosettes, quite unlike the more dubious hexagonal arrays, are associated with cellulose synthesis. Mueller and Brown (*J. Cell Biol.* 84, 315; 1980) have now confirmed the presence of such assemblies in untreated corn, pine and mung bean seedlings by freezing the material directly in solid nitrogen. They find that terminal complexes are associated with impressions made by cellulose microfibrils into the external leaflet of the lipid bilayer. It used to be said that cellulose formed a continuous meshwork without visible free ends but in one case a microfibril has been pulled through this leaflet but is still seen to terminate in the central subunit of such a complex. On the complementary protoplasmic side of the fracture, rosettes of membrane particles are commonly found. Both the rosettes and the terminal complexes are associated with the ends of microfibril impressions and it is envisaged that these could be complementary to one another such that the central subunit (which terminates the cellulose microfibril) normally sits within the rosette (Fig. 1). Once again, these investigators emphasize the importance of cellular

Clive Lloyd is in the Biosciences Division, Universities Research, Bedford.

Fig 2 Model of microfibril deposition during primary wall formation in *Micrasterias*. Above: side view. Below: surface view. Single rosettes apparently give rise to randomly oriented microfibrils. (from Giddings *et al. op. cit.*)

turgor for visualizing the terminal complexes. A brief (1 min) exposure to glycerol before freezing causes the cells to lose turgor whereupon microfibril impressions are no longer observed. An accompanying paper by Giddings, Brower and Staehelin (*J. Cell Biol.* **84**, 327; 1980) proposes a similar view of cellulose biosynthesis drawn from work on the green alga *Micrasterias denticulata*. Here, the hexagonal rosette, together with the central microfibril-terminating subunit, are pictured as a transmembrane complex responsible for the elaboration of the basic single 5 nm cellulose microfibril (Fig. 2). Rows of such complexes are believed to form sets of microfibrils which aggregate laterally to form the larger fibrils composing the secondary wall. This view of wall formation in *Micrasterias* supports that of Kiermayer and Dobberstein (Protoplasma,

77, 437; 1979) who also indicated that these specialized areas of membrane are derived by the insertion of Golgi-derived 'flat vesicles' into the plasma membrane.

These investigators are properly cautious in designating these particle complexes as the cellulose synthesizing machinery. However, if correct, the next major question for plant morphogenesis is what determines the orientation of cellulose deposition and hence plant cell shape. Perhaps the linearity of crystalline cellulose fibrils is sufficient to steer through the membrane the ordered groups of particle complexes which extrude them. On the other hand, there are grounds to believe (in higher plants) that cytoplasmic microtubules, which may be bridged to the plasma membrane, influence the orientation of cellulose deposition — but that is another story. □

To understand this object, Cash *et al.* have considered its possible relation to other interesting objects in the same region of the galactic plane. A ring of optical filaments emitting $H\alpha$ coincides with the boundary of the X-ray ring. The HEAO-1 observers suggest that the same interstellar shock which has heated the interstellar gas to produce the X-rays may be responsible for exciting these optical filaments. A large expanding loop of neutral hydrogen, one of several reported by Carl Heiles on the basis of 21 cm observations (*Astrophys. J.* **229**, 533; 1979), lies in the same direction. The most important object in the region is the group of young stars known as the Cygnus OB2 association, which lies within the boundaries of the X-ray source.

This assembly of hot and luminous stars might provide the energy for the X-ray superbubble, either through a slow sustained energy input due to violent stellar winds or by impulsive energy input from supernova explosions of the most massive stars in the association. Cash *et al.* show that a single supernova explosion would require 10^{54} erg to create the X-ray source, an energy 10^3 times larger than any observed supernova. The energy demands need not be so severe if the supernovae are frequent enough. In that case, each successive event will take place in the low density cavity blown in the interstellar gas by its predecessor. In this way, a bubble of the immense size observed with HEAO-1 could be created by several successive supernova explosions in the OB association.

The Cygnus superbubble is not the only large region of the interstellar gas which has been observed to be filled with a hot low-density medium. Reynolds and Ogden (*Astrophys. J.* **229**, 942; 1979) have examined the energetics and kinematics of a 280 parsec diameter region which is connected to the I Orion OB association that excites the Orion Nebula. Just as in the Cygnus case, faint $H\alpha$ filaments and 21 cm features outline a large soft X-ray source. Because the Orion bubble is only 460 parsec away, this object covers a full 40° on the sky. The measurements of Reynolds and Ogden show that the optical filaments are expanding at about 20 km s^{-1} . The picture in Orion, as in Cygnus, seems to be that several stars from the OB association have already lived out their lives and detonated as supernovae, carving out a large, hot bubble in the interstellar gas from their overlapping shock waves.

The idea that a substantial fraction of the interstellar medium might be maintained at a temperature of 10^6 K and a density near 10^{-2} cm^{-3} by means of overlapping supernova remnants is not new. In 1974, Cox and Smith (*Astrophys. J. Lett.* **189**, 105; 1974) pointed out that supernova explosions are frequent enough that their remnants might often connect, and more recently McKee and Ostriker (*Astrophys. J.* **218**, 148; 1977) have developed a comprehensive model for the interstellar

Interstellar violence observed

from Robert Kirshner

SUPERSONIC shocks created by stellar winds or supernova explosions are capable of heating large volumes of the interstellar gas in our Galaxy to temperatures approaching those of the solar corona. Thermal emission from this torrid interstellar medium emerges as soft X rays in the vicinity of 1 keV. The A-2 experiment on the HEAO-1 satellite spent the time from its launch in August 1977 until its demise in January 1979 in a patient effort to construct an all-sky map in soft X rays. The virtue of this approach is that it can reveal new sources in unexpected places and that it can detect very large and nearby objects that are too diffuse for imaging detectors. This scheme has paid off handsomely in the discovery of a very large (13° diameter) soft X-ray source in the constellation Cygnus which may be the fossil remains of a series of violent explosions in the interstellar gas.

As reported at a recent American Astronomical Society Meeting (San Francisco, 16 January, 1980) Webster Cash

Robert Kirshner is Assistant Professor of Astronomy at the University of Michigan.

of the University of Colorado and his collaborators from Berkeley, Caltech and the Jet Propulsion Laboratory have examined a portion of the soft X-ray survey. From their map of the Cygnus region, they find several known supernova remnants together with an immense horseshoe of emission they term an X-ray superbubble. Their data show that the emission comes from gas near 2 million K, and that there is substantial cold gas between us and the emission source which absorbs many of the X rays. From the absorption data, Cash *et al.* estimate that the distance to the giant loop of X-ray emission is about 2 kiloparsecs. Although the distance is uncertain, it implies that the diameter of the X-ray source is an astonishing 450 parsecs, 10 times larger than an ordinary supernova remnant. From the distance and the observed X-ray flux, they use the estimated temperature to derive an electron density of about 0.02 cm^{-3} , and a total thermal energy content of about $6 \times 10^{51} \text{ erg}$. This is about an order of magnitude larger than the total energy output of an ordinary supernova.

medium which predicts that coronal gas, in rough pressure equilibrium with cooler phases of interstellar gas, may fill a substantial fraction of the galactic disk. The HEAO-1 survey, and particularly the new Cygnus superbubble, provide direct evidence that the mechanisms envisioned by these theorists actually do take place. Both the Cygnus object and the Orion bubble emphasize that OB associations, where large collections of massive stars can be found, may play a prominent part in creating the overlapping supernova remnants that can fill large portions of the galaxy with coronal gas. □

Topical fusion

from M. Keith Matzen

EDWARD Teller (Lawrence Livermore Laboratory) opened a recent meeting on inertial confinement fusion (ICF)* by stressing the importance of research over premature emphasis on development. We were reminded that an ICF reactor is technologically more complex than a fission reactor, that it took 20 years to develop an economically feasible fission power plant after the demonstration of the first fission reactor, and that the first demonstration of an ICF reactor is many years away. Teller believes that there is a "small chance" that a magnetic fusion reactor could be built in this century, but that the chances of an ICF reactor in the same time are "extremely remote". On the other hand he believes that a magnetic fusion-fission hybrid could be built in about 10 years and should be pursued as an energy-producing alternative.

According to Lawrence Killion (Department of Energy, Office of Inertial Fusion) the emphasis in the ICF programme during the next decade will be to define an appropriate driver. He stated that lasers are no longer considered necessarily to be the dominant long-term driver because of their high cost and the uncertainties in the laser-target coupling. The goals for the programme in the 1980s must include the demonstration of a high-gain driver-target system, the determination of the size of a reactor driver, the understanding of driver-target coupling, the achievement of breakthroughs in driver technology, and the achievement of breakthroughs in target fabrication technology.

John Nuckolls (LL) provided further requirements and perspectives for future ICF research. The basic requirement of an ICF reactor system is an energy gain of greater than 100 with a driver energy of less than 10 MJ (10^7 Joules). Computer calculations now predict that an energy gain of 100 can be obtained with driver

energies of 2 MJ (\pm a factor of 3). He stated this energy requirement had not changed in several years, in contrast to the inflation of the driver energy required for breakeven (gain 1) targets. The increase in the break-even driver energy from 1 kJ (see *Nature* 239, 139; 1972) to the present estimate of 300 kJ (\pm a factor of 3) is due to the inability to approach the theoretical limits of the early calculations, both in laser technology and in laser-target coupling physics.

The importance of understanding the laser-target coupling physics can be illustrated by a number of key theoretical issues: fast electron transport, competition between Brillouin scattering and inverse bremsstrahlung absorption, production of fast electrons, and beam filamentation. He suggested that future experimental work should emphasize studies with longer pulse lengths and shorter wavelengths, measurements of the underdense plasma, studies of the fast electron production and transport, and studies of bandwidth effects. Although ions (both heavy and light) must solve problems of achieving sufficient power density on target, their target-coupling problems seem minimal. There is a rigorous upper limit for the ion range in a target and there are apparently no problems with fuel preheat from the electron and nuclear reactions. The problem of transporting ion beams to the target is difficult but seems to be soluble. In summary, Nuckolls gave the following estimates for the parameters of a driver for an ICF reactor: 3 MJ energy, 150 TW power, 5-10% efficient, beam focusable to less than 5 mm, 5 Hz repetition rate, cost less than 10^9 dollars, and operate for 10^{10} shots. The candidate reactor drivers are short wavelength lasers (KrF for example), heavy ion beams (HIB), and light ion beams (LIB). The drivers that may show target ignition (DT gain ~ 5 , target gain ~ 0.1) in the mid 1980s are Nova (at Lawrence Livermore Labs) and PBFA (at Sandia National Labs).

The recent emphasis in experimental programmes has been in the areas of intermediate density targets (10 times liquid DT density), techniques for measuring these compressed densities, X-ray backlighting techniques, ablative acceleration of thin foils, characterizing the back-reflected laser light, characterizing the thermal conductivity and fast-electron production by using multiple-layer targets, measuring the driver-target coupling efficiency, and experiments to examine the stability of implosion systems. With the trend towards shorter wavelength laser-drivers, several laboratories have begun experiments with doubled, tripled, and quadrupled glass laser light (wavelengths of 0.53, 0.35, and 0.26 μm , respectively). Although most experiments are still in their initial stages, the early results generally show better coupling to the target, decreased fast electron production, and better thermal conduction

as the laser wavelength decreases. However, Fred Mayer (KMS Fusion) presented measurements in which the same absorption was observed for 0.53 μm and 1.06 μm irradiation of spherical targets with 60 to 100 ps pulses. These results are in contrast to the strong wavelength dependence observed in 0.26 μm , 0.53 μm , and 1.06 μm irradiation of planar targets (Fabre *et al.*, Ecole Polytechnique Palaiseau, France). The near future will see a great deal of effort devoted to short-wavelength ($\leq 0.53 \mu\text{m}$) irradiation experiments.

ICF reactor designs are still in the conceptual stages. Protection of the reactor walls from the radiation environment is a major consideration. Several reactor designs have been considered, although flowing-liquid-metal-walled reactors have received most attention and represent the only design in which protection is provided against all the fusion reaction products. Jerry Kulcinski (University of Wisconsin) reported that work is needed in the areas of fusion reactor economics, safety and environmental impact, as well as in recovery of pellet debris, protection of final focusing elements, small LIB reactors, minimum sized HIB reactors, and pulsed neutron damage. Both Kulcinski and Noel Amherd (EPRI) stated that LIB technology appears to offer the only approach to small ICF reactors at this time. John Caird (Bechtel National, Inc.) has projected the capital cost of a HIB power plant to be from 4.2 to 6.6 billion dollars for plants in the range from 1.125 to 2.25×10^9 Watts-electrical.

With the trend towards larger, more complicated high-gain targets, the technology of target fabrication continues to be challenged. High-gain targets, in general, consist of multiple shells and larger aspect ratios (ratio of spherical shell radius to shell thickness). Thus the questions of target-shell finish and stability of implosion become more important. The technology for building these multishell targets is not yet available. At this meeting, the emphasis was on target-shell and fuel-fill characterization techniques, pellet fabrication methods and mass production of pellets. Novel approaches to target fabrication include using a low-gravity environment to form large-diameter spherical bubbles, laser drilling of 2 to 4 μm holes in microballoons, followed by gas filling and hole plugging, and structural modification of polymers to reduce crystallinity and improve the surface finish. Nondestructive fuel fill characterizations is another area of active research.

Progress on the construction of new, larger drivers continues. Nova, the 100 kJ, 1-3 ns glass facility at Lawrence Livermore Laboratory should be available for target

M Keith Matzen is in the Laser Theory Division of Sandia Laboratories, Albuquerque, New Mexico.

*The topical meeting on Inertial Confinement Fusion (ICF) was held in conjunction with the Conference on Laser and Electro-Optical Systems (CLEOS) in San Diego, California, February 26-28, 1980.

experiments in 1984. An interesting sidenote is that Shiva was operational 1 month after the earthquake in Livermore and suffered only minor damage to the optical system. At Los Alamos, the current scenario for the Antares CO₂ laser facility envisages the construction of two of the previously proposed six beam lines so that 40 kJ of CO₂ laser energy can be provided for target experiments in 1983. Recent improvements in the triple-pass amplifiers of the Helios system at Los Alamos will increase their energy on target from 5 to 10 kJ by early summer. The light-ion-beam facility at Sandia Laboratories (PBFA-1) is scheduled for completion this year and will provide 1 MJ and 30 TW. The upgrade of this facility, PBFA-II, will deliver 3.5 MJ at 100 TW and will be available for experiments in 1986. A 10-kJ heavy-ion-beam target physics facility has been proposed for construction and operation by 1984. As mentioned previously the programme for new laser development is emphasizing short wavelength lasers. The present candidates are the rare gas halide lasers KrF, XeCl, and XeF. All these require a pulse compression technique to obtain pulses in the neighbourhood of 20 ns. Papers at this meeting showed the feasibility of both Raman compression and pulse stacking (angular multiplexing) to achieve shorter pulses. A major drawback of these short-wavelength systems is the low damage threshold of the optical components and the resulting high cost of the optical system. This problem has not been adequately addressed. Since the tradeoffs between these systems will depend very strongly on the results of future laser-target coupling experiments, the option to use longer-wavelength lasers has not been eliminated. □

Thunderstorms and substorms: any connection?

from D. J. Southwood

It is a familiar fact that substantial electric fields are produced in the atmosphere during a thunderstorm. As well as a steady (d.c.) field being present, thunderstorm lightning flashes are a source of transient a.c. electromagnetic signals over a wide frequency range. A less familiar electromagnetic storm phenomenon is the magnetospheric substorm, a disturbance of the ionosphere and magnetosphere in the tenuous outer ionized layers of the Earth's atmosphere. The substorm's most dramatic manifestation is in intense

auroral displays. The aurora results from the strong electric coupling between the magnetosphere and the ionosphere below, a process which can require strong currents to flow between them. The aurora occurs when the currents are carried by energetic electron beams which give rise to light as they strike the denser lower ionosphere.

The ionosphere and magnetosphere are very good electrical conductors while the troposphere, the lowest layer of the atmosphere and the one in which thunderstorms occur, is insulating. There have been few attempts to consider whether there could be any significant electrical coupling between the troposphere and the outermost regions except by those workers (Markson *Nature* 273, 103; 1978; Herman & Goldberg *J. Atmos. Terr. Phys.* 40, 121; 1978) looking at "sun-weather relationships". The search is for causal links between activity in the tenuous outer layers of the atmosphere and the much denser bottom 5-10 km where the weather occurs. Any such connection must be subtle. The energy associated with tropospheric motions far exceeds that associated with any magnetospheric effect. Electric coupling (Markson *op. cit.*) is one possible connection.

Data from a recently reported balloon flight (Bering *et al. J. geophys. Res.* 85, 55; 1980) in northern Canada that took place during the simultaneous occurrence of a thunderstorm and a magnetospheric substorm has permitted a direct look at some interrelations between these apparently disparate disturbances in very different regions. The balloon was some 10-20 km above the top of the thunderstorm activity (at ~ 10 km) but some 60 to 70 km below the bottom of the E region ionosphere. The thunderstorm was localised and centred some 30-40 km north-west of the balloon launch site in Roberval, Quebec. In contrast the substorm was a worldwide event. Magnetograms from the USSR, Alaska, Canada and Greenland showed that magnetic perturbations due to the magnetospheric substorm were present all around the auroral zone. The balloon was instrumented to measure vertical and horizontal electric fields, electrical conductivity and X-ray emissions. The latter provide information on energetic electrons precipitated from the magnetosphere but which are stopped at much higher altitudes than the balloon's flight height. On the ground VLF (very low frequency) radio receivers, goniometers and other equipment for support measurements were deployed.

The d.c. electric field at the balloon was dominated by the presence of the thunderstorm. There are uncertainties in extrapolating the observed field upwards to the ionosphere. On this flight a reasonable estimate suggests the thunderstorm charge distribution should produce a field of 10^{-7} V m⁻¹ in the ionosphere. In contrast the detection of

echoes by the Cornell University auroral radar which was operating during the flight shows the actual ionospheric field must have exceeded 10^{-2} V m⁻¹. It seems safe to say the thunderstorm electric field had no effect on the magnetosphere and ionosphere.

Thunderstorms are a strong source of a.c. signals in the atmosphere and these can penetrate upwards far more effectively. Lightning flashes associated with the storm generate ULF (ultra low frequency) and VLF electromagnetic noise. In the 1-30 kHz VLF band lightning-flashes have long been known as a source of whistler mode plasma waves in the magnetosphere. A complicated interaction between magnetosphere and atmosphere can then be envisaged because lightning-launched whistler mode signals can interact with the magnetospheric energetic electron population. In particular, waves can scatter electrons onto orbits which bring them down into the atmosphere or lower ionosphere along the Earth's magnetic field. Here they experience collisions and in particular generate secondary X rays. The X-ray emissions seen on the balloon flight were of the microburst type, short bursts (< 1 s) which characteristically occur during substorms. A key question thus was, were any microbursts caused by lightning-induced VLF? The authors argue there were. Their test is to look at how many microbursts occur within 1.5 s of a lightning flash. 62 out of 95 nearby flashes appeared to have closely correlated bursts of electron precipitation following them. The authors estimate a 1% probability of this being chance.

The flashes also produce substantial power in the much lower ULF band (< 1 Hz). They conclude this could have a substantial effect in the ionosphere and suggest the thunderstorm-induced ionospheric ULF field could considerably exceed the substorm-induced ULF fields in the ionosphere. Whether this is of significance in magnetospheric terms is another matter. No measurements were made of magnetospheric parameters that could have been directly affected (such as ion precipitation).

The authors' most surprising measurement is that of the local electrical conductivity. It is about half its fair weather value. This certainly contradicts electrical coupling mechanisms between atmosphere and magnetosphere which invoke a substorm-induced conductivity enhancement as a trigger in a coupling mechanism.

All in all the report cuts down our ability to speculate on electric coupling of magnetosphere and atmosphere. D.C. coupling seems unimportant. The conductivity measurement is a puzzle. It does seem ULF and VLF phenomena can couple but such coupling should not be of dynamic significance in either region. The hard fact is we seem no nearer a substantive connection. □

Distributed feedback lasers

from R.G. Harrison

SINCE the gain and so the output power of most gas lasers increases as the inner diameter of the laser tube decreases, considerable attention has been given to the design of laser systems with very narrow bores. For these lasers the electromagnetic resonator modes are altered in a fundamental way from those obtained from conventional open resonator cavities formed by mirrors; the radiation field distribution being no longer determined by the mirrors but by the modes of the hollow waveguide. (Marcatili & Schmetzer, *Bell Syst. Tech. J.*, **43**, 1783; 1964). Laser oscillation is normally sustained in such systems by feedback to the tube from external mirrors. However, an alternative method recently demonstrated is that of distributed feedback (DFB) by which a forward propagating mode is coupled to its corresponding backward mode through scattering from periodic diameter or width changes in the tube. The distinctive feature of this coupling is that the scattered wave excited at a certain position in the waveguide is added in phase to the already existing wave, efficient coupling occurring only when the frequency of the ripple structure in the tube is nearly equal to twice the propagation constant of the lasing mode. Since it is not necessary that this structure be sinusoidal a convenient alternative can be provided by rectangular grooves, coupling then being provided by the fundamental frequency of the periodic rectangular ripple.

For distributed feedback systems the threshold for oscillation increases as the order of resonance of the resonant mode increases. Thus they offer the advantage of operation on the lowest order waveguide mode at a single frequency determined by the resonant mode q ; discrimination from other modes being controlled by choosing the gain of the laser such that all higher order modes than the lowest one suffer overall loss. This together with low laser thresholds and the requirement of no external optics makes the technique potentially attractive. Furthermore, the method should not be constrained by the material or cross-sectional geometry of the light tube, and as such it may be applied to many gas laser systems. These include optically pumped lasers for the near to far infrared using either dielectric or metal tubing and also transverse electrically excited high pressure systems and Stark tuned optically pumped lasers, both comprising parallel flat electrodes separated by dielectric spacers to form a rectangular section, metal-dielectric, waveguide.

Distributed feedback laser action was first reported some years back by Kogelnik

and Shank (*Appl. Phys. Letts.*, **8**, 152; 1971) for a dye system. However it was only recently that such action was achieved in a gas system (Affolter & Kneubuhl, *Phys. Lett.*, **74A**, 407; 1979) even though the theoretical foundations for such operations had been well established (Marcuse, *IEEE J. Quantum Electr.*, **QE-10**, 413, 1974; Kneubuhl, *J. Opt. Soc. Am.*, **11**, 1; 1976). Part of the reason lies in matching the laser emission with the periodic structure of the DFB waveguide. For both dye and solid state lasers there is no problem since the emission linewidth is relatively large. However, for both optically pumped and electrically excited gas lasers, usually operated at low pressures, this is not so and matching is correspondingly critical. In the preliminary work of Affolter and Kneubuhl this difficulty has been overcome by temperature tuning the periodic structure of a CH_3F optically pumped waveguide system over a temperature range between 30°C and 90°C , the temperature variation of 10°C corresponding to a relative change of $\sim 10^{-4}$ of the waveguide period. The bottom of the waveguide was periodically corrugated with rectangular grooves of depth $124\text{ }\mu\text{m}$ and period $248\text{ }\mu\text{m}$,

R.G. Harrison is in the Department of Physics, Heriot-Watt University, Edinburgh.

corresponding to a quarter and a half of the wavelength of the CH_3F emission and feedback was optimized by varying the height of the waveguide.

Evidence of DFB action was demonstrated in the resonant or mode features of the output energy of the CH_3F $496\text{ }\mu\text{m}$ emission as a function of the waveguide temperature. Single mode emission was obtained with optimum output at the centre of the temperature range. For higher pump energies oscillation of two modes was observed, peaked at temperatures separated by around 45°C , corresponding to a mode separation of 450 MHz and in agreement with DFB theory. The relatively broad temperature bandwidth of around 20°C (FWHM) over which oscillation occurs on a single mode, together with the readily accessible temperature range used in the tuning, are both particularly attractive features of the method with regard to control and operation of the system.

Whether the distributed feedback technique will eventually replace conventional cavity optics in some laser systems remains to be seen. Nevertheless these new results are promising and as such may provide the key to an accelerated effort into the research and development of such systems in the near future. □

100 years ago

In *Nature*, vol. xxi. p. III, we described the ingenious planetarium recently invented by Signor Perini, and which has cost him seven years' constant labour. To-day we are able to present an illustration of this invention, which may give those of our readers who have not seen the original, some idea of its construction. The visitors are supposed to be standing underneath the dome, from which are suspended the sun and planets.

REVIEW ARTICLES

Selfish genes, the phenotype paradigm and genome evolution

W. Ford Doolittle & Carmen Sapienza

Department of Biochemistry, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4H7

Natural selection operating within genomes will inevitably result in the appearance of DNAs with no phenotypic expression whose only 'function' is survival within genomes. Prokaryotic transposable elements and eukaryotic middle-repetitive sequences can be seen as such DNAs, and thus no phenotypic or evolutionary function need be assigned to them.

THE assertion that organisms are simply DNA's way of producing more DNA has been made so often that it is hard to remember who made it first. Certainly, Dawkins has provided the most forceful and uncompromising recent statement of this position, as well as of the position that it is the gene, and not the individual or the population, upon which natural selection acts¹. Although we may thus view genes and DNA as essentially 'selfish', most of us are, nevertheless, wedded to what we will call here the 'phenotype paradigm'—the notion that the major and perhaps only way in which a gene can ensure its own perpetuation is by ensuring the perpetuation of the organism it inhabits. Even genes such as the segregation-distorter locus of *Drosophila*², 'hitch-hiking' mutator genes in *Escherichia coli*^{3,4} and genes for parthenogenetic reproduction in many species⁴—which are so 'selfish' as to promote their own spread through a population at the ultimate expense of the evolutionary fitness of that population—are seen to operate through phenotype.

The phenotype paradigm underlies attempts to explain genome structure. There is a hierarchy of types of explanations we use in efforts to rationalize, in neo-darwinian terms, DNA sequences which do not code for protein. Untranslated messenger RNA sequences which precede, follow or interrupt protein-coding sequences are often assigned a phenotypic role in regulating messenger RNA maturation, transport or translation⁵⁻⁷. Portions of transcripts discarded in processing are considered to be required for processing⁸. Non-transcribed DNA, and in particular repetitive sequences, are thought of as regulatory or somehow essential to chromosome structure or pairing⁹⁻¹¹. When all attempts to assign to a given sequence or class of DNA functions of immediate phenotypic benefit to the organism fail, we resort to evolutionary explanations. The DNA is there because it facilitates genetic rearrangements which increase evolutionary versatility (and hence long-term phenotypic benefit)¹²⁻¹⁷, or because it is a repository from which new functional sequences can be recruited^{18,19} or, at worst, because it is the yet-to-be eliminated by-product of past chromosomal rearrangements of evolutionary significance^{9,19}.

Such interpretations of DNA structure are very often demonstrably correct; molecular biology would not otherwise be so fruitful. However, the phenotype paradigm is almost tautological; natural selection operates on DNA through organismal phenotype, so DNA structure must be of immediate or long-term (evolutionary) phenotypic benefit, even when we

cannot show how. As Gould and Lewontin note, 'the rejection of one adaptive story usually leads to its replacement by another, rather than to a suspicion that a different kind of explanation might be required. Since the range of adaptive stories is as wide as our minds are fertile, new stories can always be postulated' (ref. 20).

Non-phenotypic selection

What we propose here is that there are classes of DNA for which a 'different kind of explanation' may well be required. Natural selection does not operate on DNA only through organismal phenotype. Cells themselves are environments in which DNA sequences can replicate, mutate and so evolve²¹. Although DNA sequences which contribute to organismal phenotypic fitness or evolutionary adaptability indirectly increase their own chances of preservation, and may be maintained by classical phenotypic selection, the only selection pressure which DNAs experience directly is the pressure to survive within cells. If there are ways in which mutation can increase the probability of survival within cells without effect on organismal phenotype, then sequences whose only 'function' is self-preservation will inevitably arise and be maintained by what we call 'non-phenotypic selection'. Furthermore, if it can be shown that a given gene (region of DNA) or class of genes (regions) has evolved a strategy which increases its probability of survival within cells, then no additional (phenotypic) explanation for its origin or continued existence is required.

This proposal is not altogether new; Dawkins¹, Crick⁶ and Bodmer²² have briefly alluded to it.

However, there has been no systematic attempt to describe elements of prokaryotic and eukaryotic genomes as products of non-phenotypic selection whose primary and often only function is self-preservation.

Transposable elements in prokaryotes as selfish DNA

Insertion sequences and transposons can in general be inserted into a large number of chromosomal (or plasmid) sites, can be excised precisely or imprecisely and can engender deletions

or inversions in neighbouring chromosomal (or plasmid) DNAs¹²⁻¹⁶. These behaviours and, at least in some cases, the genetic information for the enzymatic machinery involved, must be inherent in the primary sequences of the transposable elements themselves, which are usually tightly conserved^{12-16,23}. Most speculations on the function of transposable elements concentrate on the role these may have, through chromosomal rearrangements and the modular assembly of different functional units, in promoting the evolution of plasmid and bacterial chromosomes, and thus in promoting long-term phenotypic fitness¹²⁻¹⁶. Most assume that it is for just such functions that natural selection has fashioned these unusual nucleic acid sequences.

Although transposable elements may well be beneficially involved in prokaryotic evolution, there are two reasons to doubt that they arose or are maintained by selection pressures for such evolutionary functions.

First, DNAs without immediate phenotypic benefit are of no immediate selective advantage to their possessor. Excess DNA should represent an energetic burden^{24,25}, and some of the activities of transposable elements are frankly destructive¹²⁻¹⁶. Evolution is not anticipatory; structures do not evolve because they might later prove useful. The selective advantage represented by evolutionary adaptability seems far too remote to ensure the maintenance, let alone to direct the formation, of the DNA sequences and/or enzymatic machinery involved. A formally identical theoretical difficulty plagues our understanding of the origin of sexual reproduction, even though this process may now clearly be evolutionarily advantageous^{1,4}.

Second, transposability itself ensures the survival of the transposed element, regardless of effects on organismal phenotype or evolutionary adaptability (unless these are sufficiently negative). Thus, no other explanation for the origin and maintenance of transposable elements is necessary. A single copy of a DNA sequence of no phenotypic benefit to the host risks deletion, but a sequence which spawns copies of itself elsewhere in the genome can only be eradicated by simultaneous multiple deletions. Simple translocation (removal from one site and insertion into another) does not provide such insurance against deletion. It is significant that recent models for transposition require retention of the parental sequence copy^{26,27}, and that bacterial insertion sequences are characteristically present in several copies per genome¹⁶. The assumption that transposable elements are maintained by selection acting on the cell does not require that they show these characteristics. The evolutionary behaviour of individual copies of transposable elements within the environment represented by a bacterial genome and its descendants can be understood in the same terms as organismal evolution. Replicate copies of a given element may diverge in sequence, but at least those features of sequence required for transposition will be maintained by (non-phenotypic) selection; copies which can no longer be translocated will eventually suffer elimination. Some divergent copies may be more readily transposed; these will increase in frequency at the expense of others. Transposable elements which depend on host functions run the risk that host mutants will no longer transpose them; it is significant that at least some transposition-specific functions are known to be coded for by the transposable elements themselves²⁶⁻²⁹. It is not to the advantage of a transposable element coding for such functions to promote the transposition of unrelated elements; the fact that given transposable elements generate flanking repeats^{16,30} of chromosomal DNAs of sizes characteristic to them (that is, 5, 9 or 11-12 base pairs) may indicate such a specificity in transposition mechanism. It is to the advantage of any transposable element to acquire genes which allow independent replication (to become a plasmid), promote host mating (to become a self-transmissible plasmid) or promote non-conjugational transmission (to become a phage like Mu).

It is certainly not novel to suggest that prokaryotic transposable elements behave in these ways, or to suggest that more frankly autonomous entities like phages have arisen from

them^{12-16,31}. However, we think it has not been sufficiently emphasized that non-phenotypic selection may inevitably give rise to transposable elements and that no phenotypic rationale for their origin and continued existence is thus required.

Transposable elements in eukaryotes

There has long been genetic evidence for the existence in eukaryotic genomes of transposable elements affecting phenotype³². These have been assigned roles in the regulation of eukaryotic gene expression and in evolution, but would have escaped genetic detection had they not had phenotypic effect. More recent evidence for transposable elements whose effects are not readily identified genetically has come fortuitously from studies of cloned eukaryotic DNAs. For instance, the Ty-1 element of yeast (which has no known phenotypic function) is flanked by direct repeats (like some prokaryotic transposons) and is transposable³³. It is present in some 35 dispersed copies and comprises some 2% of the yeast genome (like a higher-eukaryotic middle-repetitive DNA). The directly repeated δ -sequence elements flanking it are found at still other sites (just as prokaryotic insertion sequences can be found flanking transposons or independently elsewhere in the genome). Cameron *et al.* suggest that 'Ty-1 may be a nonviral "parasitic" DNA' but then go on to suggest, we think unnecessarily, that transposition 'allows adaptation of a particular cell to a new environment' (ref. 33). The repetitive elements 412, copia and 297 of *Drosophila* are physically similar to Ty-1 (and to bacterial transposable elements) and are transposable³⁴⁻³⁷. Strobel *et al.* suggest 'it is possible that the sole function of these elements is to promote genetic variability, and that their gene products may only be necessary for the maintenance and mobility of the elements themselves, rather than for other cellular processes' (ref. 37). But if maintenance and mobility mechanisms exist, then no cellular function at all need be postulated.

A large fraction of many eukaryotic genomes consists of middle-repetitive DNAs, and the variety and patterns of their interspersions with unique sequence DNA make no particular phylogenetic or phenotypically functional sense. Britten, Davidson and collaborators have elaborated models which ascribe regulatory functions to middle-repetitive DNAs, and evolutionary advantage (in terms of adaptability) to the quantitative and qualitative changes in middle-repetitive DNA content observed even between closely related species^{17,38-40}. Middle-repetitive DNAs are more conserved in sequence during evolution than are unique-sequence DNAs not coding for protein, and Klein *et al.* suggest that 'restraint on repetitive sequence divergence, either within the repeat families of a given species, or over evolutionary time spanning the emergence of different species, could be due to [phenotypic] selective pressures which prevent free sequence change in a large fraction of the repeat family members. Or perhaps repetitive sequences diverge as rapidly as do other sequences, but the type sequence of the family is preserved by frequent remultiplication of the "correct" surviving sequences' (ref. 41). The evidence for a phenotypically functional role for middle-repetitive sequences remains dishearteningly weak⁴⁰⁻⁴³, and if the calculations of Kimura⁴⁴ and Salser and Isaacson⁴⁵ are correct, middle-repetitive DNAs together comprise too large a fraction of most eukaryotic genomes to be kept accurate by darwinian selection operating on organismal phenotype. The most plausible form of "remultiplication of the 'correct' surviving sequences" is transposition. If we assume middle-repetitive DNAs in general to be transposable elements or degenerate (and no longer transposable and ultimately to be eliminated) descendants of such elements, then the observed spectra of sequence divergence within families and changes in middle-repetitive DNA family sequence and abundance can all be explained as the result of non-phenotypic selection within genomes. No cellular function at all is required to explain either the behaviour or the persistence of middle-repetitive sequences as a class.

The rest of the eukaryotic genome

Middle-repetitive DNA can comprise more than 30% of the genome of a eukaryotic cell⁴⁶. Another 1–40% consists of simple reiterated sequences whose functions remain unclear¹⁰, and Smith has argued that 'a pattern of tandem repeats is the natural state of DNA whose sequence is not maintained by selection' (ref. 47). Even unique-sequence eukaryotic DNA consists in large part of elements which do not seem to be constrained by phenotypic selection pressures⁴⁵. Some authors have argued that the intervening sequences which interrupt many eukaryotic structural genes are insertion sequence-like elements^{6,48,49}. If they are, they are likely to be the degenerate and no-longer-transposable descendants of transposable sequences whose insertion was rendered non-lethal by pre-existing cellular RNA:RNA splicing mechanisms. Such elements, once inserted, are relatively immune to deletion (since only very precise deletion can be non-lethal), and need retain only those sequence components required for RNA splicing. The rest of the element is free to drift and one expects (and observes) that only the position and number of intervening sequences in a family of homologous genes remain constant during evolution. Although evolutionary and regulatory phenotypic functions have been ascribed to intervening sequences^{6,49–51}, it is unnecessary to postulate any cellular function at all if these elements are indeed degenerate transposable elements arising initially from non-phenotypic selection. Another explanation for the origin and continued existence of intervening sequences, which also does not require phenotypically or evolutionarily advantageous roles, has been suggested elsewhere^{50,51}.

Why do prokaryotes and eukaryotes differ?

It is generally believed that prokaryotic genomes consist almost entirely of unique-sequence DNA maintained by phenotypic selection, whereas the possession of 'excess' unique and repetitive DNA sequences whose presence is at least difficult to rationalize in phenotypic terms is characteristic of eukaryotes. However, it is more accurate to say that there is a continuum of excess DNA contents; at least 1% of the *E. coli* genome can be made up of copies of six identified insertion sequences alone¹⁶. Yeast, whose genome is no larger than that of some prokaryotes, has few repeated sequences other than those coding for stable RNAs, and *Aspergillus* may have none^{52,53}. There is in general (but with many exceptions) a positive correlation between excess DNA content, genome size and what we anthropocentrically perceive as 'evolutionary advancement'. Many interpret

this as the cause and/or consequence of the increasing phenotypic complexity which characterizes organismal evolution, and attribute to excess DNA a positive role in the evolutionary process^{17–19,40}. The interplay of phenotypic and non-phenotypic forces, and the importance of understanding both in attempts to restore the 'C-value paradox' are discussed more thoroughly by Orgel and Crick in the following article.⁵⁴

There is another, simpler and perhaps obvious explanation. Non-phenotypic selection produces excess DNA, and excess DNA logically must be an energetic burden; phenotypic selection should favour its elimination^{24,25}. The amount of excess (and hence total) DNA in an organism should be loosely determined by the relative intensities of the two opposing sorts of selection. The intensity of non-phenotypic pressure on DNA to survive even without function should be independent of organismal physiology. The intensity of phenotypic selection pressure to eliminate excess DNA is not, this being greatest in organisms for which DNA replication comprises the greatest fraction of total energy expenditure. Prokaryotes in general are smaller and replicate themselves and their DNA more often than eukaryotes (especially complex multicellular eukaryotes). Phenotypic selection pressure for small 'streamlined' prokaryotic genomes with little excess DNA may be very strong.

Necessary and unnecessary explanations

We do not deny that prokaryotic transposable elements or repetitive and unique-sequence DNAs not coding for protein in eukaryotes may have roles of immediate phenotypic benefit to the organism. Nor do we deny roles for these elements in the evolutionary process. We do question the almost automatic invocation of such roles for DNAs whose function is not obvious, when another and perhaps simpler explanation for their origin and maintenance is possible. It is inevitable that natural selection of the special sort we call non-phenotypic will favour the development within genomes of DNAs whose only 'function' is survival within genomes. When a given DNA, or class of DNAs, of unproven phenotypic function can be shown to have evolved a strategy (such as transposition) which ensures its genomic survival, then no other explanation for its existence is necessary. The search for other explanations may prove, if not intellectually sterile, ultimately futile.

We thank L. Bonen, R. M. MacKay and M. Schnare for help in development of the ideas presented here, and C. W. Helleiner, M. W. Gray, C. Stuttard, R. Singer, S. D. Wainwright and E. Butz for critical discussions.

We are especially grateful to C.E. Orgel and F.H.C. Crick for discussing with us the ideas presented in the following article before publication and for encouragement and support.

Selfish DNA: the ultimate parasite

L. E. Orgel & F. H. C. Crick

The Salk Institute, 10010 N. Torrey Pines Road, La Jolla, California 92037

The DNA of higher organisms usually falls into two classes, one specific and the other comparatively nonspecific. It seems plausible that most of the latter originated by the spreading of sequences which had little or no effect on the phenotype. We examine this idea from the point of view of the natural selection of preferred replicators within the genome.

THE object of this short review is to make widely known the idea of selfish DNA. A piece of selfish DNA, in its purest form, has two distinct properties:

- (1) It arises when a DNA sequence spreads by forming additional copies of itself within the genome.
- (2) It makes no specific contribution to the phenotype.

This idea is not new. We have not attempted to trace it back to its roots. It is sketched briefly but clearly by Dawkins¹ in his book *The Selfish Gene* (page 47). The extended discussion (pages 39–45) after P. M. B. Walker's article² in the CIBA volume based on a Symposium on Human Genetics held in June 1978 shows that it was at that time already familiar to Bodmer, Fincham and one of us. That discussion referred specifically to repetitive DNA because that was the topic of Walker's article, but we shall use the term selfish DNA in a wider sense, so that it can refer not only to obviously repetitive DNA but also to certain other DNA sequences which appear to have little or no function, such as much of the DNA in the introns of genes and parts of the DNA sequences between genes. The catch-phrase 'selfish DNA' has already been mentioned briefly on two occasions^{3,4}. Doolittle and Sapienza⁵ (see the previous article) have independently arrived at similar ideas.

The amount of DNA

The large amounts of DNA in the cells of most higher organisms and, in particular, the exceptionally large amounts in certain animal and plant species—the so-called *C* value paradox—has been an unsolved puzzle for a considerable period (see reviews in refs 6–8). As is well known, this DNA consists in part of 'simple' sequences, an extreme example of which is the very large amounts of fairly pure poly d(AT) in certain crabs. Simple sequences, which are situated in chromosomes largely but not entirely in the heterochromatin, are usually not transcribed. Another class of repetitive sequences, the so-called 'intermediate repetitive', have much longer and less regular repeats. Such sequences are interspersed with 'unique' DNA at many places in the chromosome, the precise pattern of interspersions being to some extent different in different species. Leaving aside genes which code for structural RNA of one sort or another (such as transfer RNA and ribosomal RNA), which would be expected to occur in multiple copies (since, unlike protein, their final products are the result of only one stage of magnification, not two), the majority of genes coding for proteins appear to exist in 'single' copies, meaning here one or a few. A typical example would be the genes for α -globin, which occur in one to three copies and the human β -like globins, of which there are four main types, all related to each other but used for slightly different purposes. Notable exceptions are the proteins of the immune system, and probably those of the histocompatibility and related systems. Another exception is the genes for the five major types of histone which also occur in multiple copies. Even allowing for all such special case, the estimated number of genes in the human genome appears too few to account for the 3×10^9 base pairs found per haploid set of DNA, although it must be admitted that all such arguments are very far from conclusive.

Several authors^{8–13} have suggested that the DNA of higher organisms consists of a minority of sequences with highly specific

functions plus a majority with little or no specificity. Even some of the so-called single-copy DNA may have no specific function. A striking example comes from the study of two rather similar species of *Xenopus*. These can form viable hybrids, although these hybrids are usually sterile. However, detailed molecular hybridization studies show that there has been a large amount of DNA sequence divergence since the evolutionary separation of their forebears. These authors¹³ conclude 'only one interpretation seems reasonable, and that is that the specific sequence of much of the single-copy DNA is not functionally required during the life of the animal. This is not to say that this DNA is functionless, only that its specific sequence is not important'.

There is also evidence to suggest that the majority of DNA sequences in most higher organisms do not code for protein since they do not occur at all in messenger RNA (for reviews see refs 14, 15). Nor is it very plausible that all this extra DNA is needed for gene control, although some portion of it certainly must be.

We also have to account for the vast amount of DNA found in certain species, such as lilies and salamanders, which may amount to as much as 20 times that found in the human genome. It seems totally implausible that the number of radically different genes needed in a salamander is 20 times that in a man. Nor is there evidence to support the idea that salamander genes are mostly present in about 20 fairly similar copies. The conviction has been growing that much of this extra DNA is 'junk', in other words, that it has little specificity and conveys little or no selective advantage to the organism.

Another place where there appears to be more nucleic acid than one might expect is in the primary transcripts of the DNA of higher organisms which are found in the so-called heteronuclear RNA. It has been known for some time that this RNA is typically longer than the messenger RNA molecules found in the corresponding cytoplasm. Heteronuclear RNA contains these messenger RNA sequences but has many other sequences which are never found in the cytoplasm. The phenomenon has been somewhat clarified by the recent discovery of introns in many genes (for a general introduction see ref. 4). Although the evidence is still very preliminary, it certainly suggests that much of the base sequence in the interior of some introns may be junk, in that these sequences drift rapidly in evolution, both in detail and in size. Moreover, the number of introns may differ even in closely related genes, as in the two genes for rat preproinsulin¹⁶. Whether there is junk between genes is unclear but it is noteworthy that the four genes for the human β -like globins, which occur fairly near together in a single stretch of DNA, occupy a region no less than 40 kilobases long¹⁷. This greatly exceeds the total length of the four primary transcripts (that is the four mRNA precursors), an amount estimated to be considerably less than 10 kilobases. There is little evidence to indicate that there are other coding sequences between these genes (although the question is still quite open) and a tenable hypothesis is that much of this interspersed DNA has little specific function.

In summary, then, there is a large amount of evidence which suggests, but does not prove, that much DNA in higher

organisms is little better than junk. We shall assume, for the rest of this article, that this hypothesis is true. We therefore need to explain how such DNA arose in the first place and why it is not speedily eliminated, since, by definition, it contributes little or nothing to the fitness of the organism.

What is selfish DNA?

The theory of natural selection, in its more general formulation, deals with the competition between replicating entities. It shows that, in such a competition, the more efficient replicators increase in number at the expense of their less efficient competitors. After a sufficient time, only the most efficient replicators survive. The idea of selfish DNA is firmly based on this general theory of natural selection, but it deals with selection in an unfamiliar context.

The familiar neo-darwinian theory of natural selection is concerned with the competition between organisms in a population. At the level of molecular genetics it provides an explanation of the spread of 'useful' genes or DNA sequences within a population. Organisms that carry a gene that contributes positively to fitness tend to increase their representation at the expense of organisms lacking that gene. In time, only those organisms that carry the useful gene survive. Natural selection also predicts the spread of a gene or other DNA sequence within a single genome, provided certain conditions are satisfied. If an organism carrying several copies of the sequence is fitter than an organism carrying a single copy, and if mechanisms exist for the multiplication of the relevant sequence, then natural selection must lead to the emergence of a population in which the sequence is represented several times in every genome.

The idea of selfish DNA is different. It is again concerned with the spread of a given DNA within the genome. However, in the case of selfish DNA, the sequence which spreads makes no contribution to the phenotype of the organism, except insofar as it is a slight burden to the cell that contains it. Selfish DNA sequences may be transcribed in some cases and not in others. The spread of selfish DNA sequences within the genome can be compared to the spread of a not-too-harmful parasite within its host.

Mechanisms for DNA spreading

The inheritance of a repeated DNA sequence in a population of eukaryotes clearly requires that the multiplication which produced it occurred in the germ line. Furthermore, any mechanism that can lead to the multiplication of useful DNA will probably lead to the multiplication of selfish DNA (and vice versa). Of course, natural selection subsequently discriminates between multiple sequences of different kinds, but it does not necessarily prevent the multiplication of neutral or harmful sequences.

Multiplication in the germ-line sequence can occur in non-dividing cells or during meiosis and mitosis (within lineages that lead to the germ line). In the former case, the mechanisms available resemble those that are well documented for prokaryotes, that is, multiplication may occur in eukaryotes through the integration of viruses or of elements analogous to transposons and insertion sequences. Doolittle and Sapienza⁵ have discussed these mechanisms in some detail, particularly for prokaryotes. They are likely to lead to the spreading of DNA sequences to widely separated positions on the chromosomes.

During mitosis and meiosis, multiplication (or deletion) is likely to occur by unequal crossing over. This mechanism will often lead to the formation of tandem repeats. It is well documented for the tRNA 'genes' of *Drosophila* and for various other tandemly repeated sequences in higher organisms.

The amount and location of selfish DNA

Natural selection 'within' the genome will favour the indefinite spreading of selfish preferred replicators. Natural selection between genotypes provides a balancing force that attempts to maintain the total amount of selfish DNA at an equilibrium (steady state) level—organisms whose genomes contain an

excessive proportion of selfish DNA would be at a metabolic disadvantage relative to organisms with less selfish DNA, and so would be eliminated by the normal mechanism of natural selection. Excessive spreading of functionless replicators may be considered as a 'cancer' of the genome—the uncontrolled expansion of one segment of the genome would ultimately lead to the extinction of the genotype that permits such expansion. Of course, we do not know whether extinction of genotypes in nature even occurs for this reason.

It is hard to get beyond generalities of this kind. To do so we would, at least, need to know how much selective disadvantage results from the presence of a given amount of useless DNA. Even this minimal information is not easily acquired, so we cannot produce other than qualitative arguments.

It seems certain that the metabolic energy cost of replicating a superfluous short DNA sequence in a genome containing 10^9 base pairs would be very small. If, for example, the selective advantage were equal to the proportion of the genome made up by the extra DNA, a sequence of 1,000 base pairs would produce a selective disadvantage of only 10^{-6} . If the selective disadvantage were proportional to the extra energy cost divided by the total metabolic energy expended per cell per generation, the disadvantage would be much smaller. The selective disadvantage might be greater in more stringent conditions, but it is still hard to believe that a relatively small proportion of selfish DNA could be selected against strongly.

On the other hand, when the total amount of selfish DNA becomes comparable to or greater than that of useful DNA, it seems likely that the selective disadvantage would be significant. We may expect, therefore, that the mechanisms for the formation and deletion of nonspecific DNA will adjust, in each organism, so that the load of DNA is sufficiently small that it can be accommodated without producing a large selective disadvantage. The proportion of nonspecific DNA in any particular organism will thus depend on the lifestyle of the organism, and particularly on its sensitivity to metabolic stress during the most vulnerable part of the life cycle.

We can make one prediction on the basis of energy costs. Selfish DNA will accumulate to a greater extent in non-transcribed regions of the genome than in those that are transcribed. Of course, selfish DNA will in most cases be excluded from translated sequences, because the insertion of amino acids within a protein will almost always have serious consequences, even in diploid organisms (but see the suggestion by F.H.C.C.¹⁸).

At first sight it might seem anomalous that natural selection does not eliminate all selfish DNA. Since the suggestion that much eukaryotic DNA is useless distinguishes the selfish DNA hypothesis from many closely related proposals, it may be useful to take up this point in some detail.

First, the elimination of disadvantaged organisms from a population, by their more favoured competitors, takes a number of generations several times larger than the reciprocal of the selective disadvantage. If the selective disadvantage associated with a stretch of useless DNA in higher organisms is only 10^{-6} , it would take 10^6 – 10^8 years to eliminate it by competition. For typical higher organisms this is a very long time, so the elimination of a particular stretch of selfish DNA may be a very slow process even on a geological time scale. Second, the mechanisms for the deletion of short sequences of DNA may be inefficient, since there is no strong selective pressure for the development of 'corrective' measures when the 'fault' carries a relatively small selective penalty. Taken together, these arguments suggest that the elimination of a particular piece of junk from the genome may be a very slow process.

This in turn suggests that the amount of useless DNA in the genome is a consequence of a dynamic balance. The organism 'attempts' to limit the spread of selfish DNA by controlling the mechanism for gene duplication, but is constrained by imperfections in genetic processes and/or by the need to permit some duplication of advantageous genes. Selfish DNA sequences 'attempt' to subvert these mechanisms and may be able to do so

comparatively rapidly because mutation will affect them directly. On the other hand, the defence mechanisms of the host are likely to depend on the action of protein and therefore may evolve more slowly. Once established within the genome, useless sequences probably have a long 'life expectancy'.

For any particular type of selfish DNA, there is no reason that a steady state should necessarily be reached in evolution. The situation would be continually changing. A particular type of DNA might first spread rather successfully over the chromosomes. The host might then evolve a mechanism which reduced or eliminated further spreading. It might also evolve a method for preferentially deleting it. At the same time, random mutations in the selfish DNA might make it more like ordinary DNA and so, perhaps, less easy to remove. Eventually, these sequences, possibly by now rather remote from those originally introduced, may cease to spread and be slowly eliminated. Meanwhile, other types of selfish DNA may originate, expand and evolve in a similar way.

In short, we may expect a kind of molecular struggle for existence within the DNA of the chromosomes, using the process of natural selection. There is no reason to believe that this is likely to be much simpler or more easy to predict than evolution at any other level. At bottom, the existence of selfish DNA is possible because DNA is a molecule which is replicated very easily and because selfish DNA occurs in an environment in which DNA replication is a necessity. It thus has the opportunity of subverting these essential mechanisms to its own purpose.

The inheritance of selfish DNA

Although the inheritance of selfish DNA will occur mainly within a mendelian framework, it is likely to be different in detail and more complex than simple mendelian inheritance. This is due both to the multiplication mechanisms, which in one way or another will produce repeated copies (see the discussion by Doolittle and Sapienza⁵), and to the fact that these copies are likely to be distributed round the chromosomes rather than being located in a single place in the genome as most normal genes are. For both these reasons, a particular type of selfish DNA is likely to spread more rapidly through a population than would a normal gene with a low selective advantage. It will be even more rapid if selfish DNA can spread horizontally between different individuals in a population, due to viruses or other infectious agents, although it should be remembered that such 'infection' must affect the germ line and not merely the soma. If this initial spread takes place when the additional DNA produced is relatively small in amount, it is unlikely to be seriously hindered by the organism selecting against it. The study of these processes will clearly require a new type of population genetics.

Can selfish DNA acquire a specific function?

It would be surprising if the host organism did not occasionally find some use for particular selfish DNA sequences, especially if there were many different sequences widely distributed over the chromosomes. One obvious use, as repeatedly stressed by Britten and Davidson^{19,20}, would be for control purposes at one level or another. This seems more than plausible.

It has often been argued (see, for example, ref. 21) that for the evolution of complex higher organisms, what is required is not so much the evolution of new proteins as the evolution of new control mechanisms and especially mechanisms which control together sets of genes which previously had been regulated separately. To be useful, a new control sequence on the DNA is likely to be needed in a number of distinct places in the genome. It has rarely been considered how this could be brought about expeditiously by the rather random methods available to natural selection.

A mechanism which scattered, more or less at random, many kinds of repeated sequences in many places in the genome would appear to be rather good for this purpose. Most sets of such sequences would be unlikely to find themselves in the right

combination of places to be useful but, by chance, the members of one particular set might be located so that they could be used to turn on (or turn off) together a set of genes which had never been controlled before in a coordinated way. A next way of doing this would be to use as control sequences not the many identical copies distributed over the genome, but a small subset of these which had mutated away from the master sequence in the same manner.

On this picture, each set of repeated sequences might be 'tested' from time to time in evolution by the production of a control macromolecule (for example, a special protein) to recognize those sequences. If this produced a favourable result, natural selection would confirm and extend the new mechanism. If not, it would be selected against and discarded. Such a process implies that most sets of repeated sequences will never be of use since, on statistical grounds, their members will usually be in unsuitable places.

It thus seems unlikely that all selfish DNA has acquired a special function, especially in those organisms with very high *C* values. Nor do we feel that if one example of a particular sequence acquires a function, all the copies of that sequence will necessarily do so. As selfish DNA is likely to be distributed over the chromosomes in rather a random manner, it seems unlikely that every copy of a potentially useful sequence will be in the right position to function correctly. For example, if a specific sequence within an intron were used to control the act of splicing that intron, a similar sequence in an untranscribed region between genes would obviously not be able to act in this way.

In some circumstances, the sheer bulk of selfish DNA may be used by the organism for its own purpose. That is, the selfish DNA may acquire a nonspecific function which gives the organism a selective advantage. This is the point of view favoured by Cavalier-Smith in a very detailed and suggestive article¹² which the reader should consult. He proposes that excess DNA may be the mechanism the cell uses to slow up development or to make bigger cells. However, we suspect that both slow growth and large cell size could be evolved just as well by other more direct mechanisms. We prefer to think that the organism has tolerated selfish DNA which has arisen because of the latter's own selective pressure.

Thus, some selfish DNA may acquire a useful function and confer a selective advantage on the organism. Using the analogy of parasitism, slightly harmful infestation may ultimately be transformed into a symbiosis. What we would stress is that not all selfish DNA is likely to become useful. Much of it may have no specific function at all. It would be folly in such cases to hunt obsessively for one. To continue our analogy, it is difficult to accept the idea that all human parasites have been selected by human beings for their own advantage.

Life style

The effect of nonspecific DNA on the life style of the organism has been considered by several authors, in particular by Cavalier-Smith¹² and by Hindergardner⁸. We shall not attempt to review all their ideas here but instead will give one example to show the type of argument used.

Bennett²² has brought together the measurements of DNA content for higher herbaceous plants. There is a striking connection between DNA content per cell and the minimum generation time of the plant. In brief, if such an angiosperm has more than 10 pg of DNA per cell, it is unlikely to be an ephemeral (that is, a plant with a short generation time). If it is a diploid and has more than 30 pg of DNA, it is highly likely to be an obligate perennial, rather than an annual or an ephemeral. The converse, however, is not true, there being a fair number of perennials with a DNA content of less than 30 pg and a few with less than 10 pg. A clear picture emerges that if a herbaceous plant has too much DNA it cannot have a short generation time.

This is explained by assuming that the extra DNA needs a bigger nucleus to hold it and that this increases both the size of the cell and the duration of meiosis and generally slows up the development of the plant. An interesting exception is that the

duration of meiosis, is, if anything, shorter for polyploid species than for their diploid ancestors²³. This suggests that it is the ratio of good DNA to junk DNA rather than the total DNA content which influences the duration of meiosis.

An analogous situation may obtain in certain American species of salamander. These often differ considerably in the rapidity of their development and of their life cycles, the tropical species tending to take longer than the more temperate ones. Drs David Wake and Herbert MacGregor (personal communication) tell us that preliminary evidence suggests that species with the longer developmental times often have the higher *C* values. This appears to parallel the situation just described for the herbaceous plants. It remains to be seen if further evidence will continue to support this generalization. (See the interesting paper by Oeldorfe *et al.*²⁵ on 25 species of frogs. They conclude that 'genome size sets a limit beyond which development cannot be accelerated'.)

Testing the theory

The theory of selfish DNA is not so vague that it cannot be tested. We can think of three general ways to do this. In the first place, it is important to know where DNA sequences occur which appear to have little obvious function, whether they are associated with flanking or other sequences of any special sort and how homologous sequences differ in different organisms and in different species, either in sequence or in position on the chromosome. For example, it has recently been shown by Young²⁴ that certain intermediate repetitive sequences in *Drosophila* are often in different chromosomal positions in different strains of the same species.

Second, if the increase of selfish DNA and its movement around the chromosome are not rare events in evolution, it may be feasible to study, in laboratory experiments, the actual molecular mechanisms involved in these processes.

Third, one would hope that a careful study of all the nonspecific effects of extra DNA would give us a better idea of how it affected different aspects of cellular behaviour. In parti-

cular, it is important to discover whether the addition of nonspecific DNA does, in fact, slow down cells metabolically and for what reasons. Such information, together with a careful study of the physiology and life style of related organisms with dissimilar amounts of DNA, should eventually make it possible to explain these differences in a convincing way.

Conclusion

Although it is an old idea that much DNA in higher organisms has no specific function⁸⁻¹², and although it has been suggested before that this nonspecific DNA may rise to levels which are acceptable or even advantageous to an organism^{8,12}, depending on certain features of its life style, we feel that to regard much of this nonspecific DNA as selfish DNA is genuinely different from most earlier proposals. Such a point of view is especially useful in thinking about the dynamic aspects of nonspecific DNA. It directs attention to the mechanisms involved in the spread and evolution of such DNA and it cautions one against looking for a special function for every piece of DNA which drifts rapidly in sequence or in position on the genome.

While proper care should be exercised both in labelling as selfish DNA every piece of DNA whose function is not immediately apparent and in invoking plausible but unproven hypotheses concerning the details of natural selection, the idea seems a useful one to bear in mind when exploring the complexities of the genomes of higher organisms. It could well make sense of many of the puzzles and paradoxes which have arisen over the last 10 or 15 years. The main facts are, at first sight, so odd that only a somewhat unconventional idea is likely to explain them.

We thank W. Ford Doolittle and C. Sapienza for showing us their article before publication, and Drs D. Wake and H. Macgregor for allowing us to quote some of their unpublished conclusions about salamanders. This work was supported by the Eugene and Estelle Ferhauf Foundation, the J. W. Kieckhefer Foundation, the Ahmanson Foundation and the Samuel Roberts Noble Foundation.

Observations of γ rays of 1–20 MeV with the UCR Compton double scatter γ ray telescope are reported for a balloon flight launched from Palestine, Texas, 4.5 GV, at 01.00 UT 29 September 1978. The energy distribution of the total γ rays from the Crab from 1.2 to 20 MeV is measured. Two σ upper limits of 3, 2, 0.6 and 0.4×10^{-4} photons $\text{cm}^{-2} \text{s}^{-1} \text{MeV}^{-1}$ at energies 1.2–3, 3–5, 5–10 and 10–20 MeV, respectively, are found for the Seyfert galaxy NGC4151, the black hole candidate Cyg X-1 and for Cyg X-3. In the same energy intervals, the 2σ upper limits for the nearest and second nearest QSOs CG135+1 and 3C273 are 5, 3, 1 and 0.4×10^{-4} photons $\text{cm}^{-2} \text{s}^{-1} \text{MeV}^{-1}$. These upper limits restrict confirmed γ -ray sources at 1–20 MeV to the Crab and NP0532. Our upper limits for NGC4151 do not support Seyfert galaxies as the source of cosmic diffuse radiation¹.

The University of California UCR Compton double scatter γ -ray telescope measures the energy of the incident γ ray and its scatter angle in the first scintillator. The method of detection, efficiencies and time, angle and energy resolutions have been described previously^{2,3}. Vertical pairs of cells, only, are used in this analysis. Thus, the scatter angle is equal to the zenith angle and the zenith angle of the source is determined for each observed γ ray as a circle on the sky. The sky is divided into circles around the zenith and γ rays are collected into bins in zenith angle and energy. Because of low telescope efficiencies at small angles, $\leq 10^\circ$, and higher backgrounds at large angles $\geq 30^\circ$, we report here only γ rays with zenith angles between 10 and 30° .

Although corrections were made for gain changes in the energy and angle assignments, telescope thresholds are also affected. Therefore, we chose the computer thresholds high enough, 0.3 and 0.9 MeV for S1 and S2, to be above the electronic thresholds throughout most of the flight. Near the beginning of the flight, however, just after reaching the ceiling limit, the computer thresholds were below the actual ones for the small angle scatters and some real γ rays were rejected. The effect is greatest for the $10\text{--}20^\circ$ scatters so we have used no $10\text{--}20^\circ$ data until 30 September 13.00 UT. From 30 September 09.30 UT to flight termination, the residual atmosphere ranged between 4.5 and 3.2 g cm^{-2} . The downward-moving γ -ray background is a combination of atmospheric, cosmic diffuse and neutron-induced γ rays. The cosmic diffuse and neutron-induced backgrounds are nearly independent of height in the atmosphere but we need to correct for the atmospheric γ rays that vary nearly linearly with depth.

The Crab, NGC4151 and 3C273 crossed the zenith meridian at 11.15, 14.75 and 18.15 UT, respectively, 30 September and 1 October; Cyg X-1 and Cyg X-3 transited at 01.45 and 02.30 UT, respectively, 30 September; and CG135+1 transited at 18.00 UT on 1 October as shown in Fig. 1. With few exceptions, observations were made continuously from 09.30 UT on 30 September to 23.00 UT on 1 October.

The count rates for γ rays of 1.2–10 MeV, corrected for altitude variation, were combined into 30-min intervals and plotted in Fig. 1. The data for zenith angles of $10\text{--}20^\circ$ and $20\text{--}30^\circ$ are shown for the duration of the flight at float. As the Earth turns on its axis, a celestial point source passes through the $10\text{--}20^\circ$ and $20\text{--}30^\circ$ telescope zenith angle rings on the sky. The expected shapes of the count rates from a point source are shown by the solid contours.

The background for the Crab has been chosen as an average fit to the data from 30 September, 15.00 UT to 1 October, 07.00 UT and 1 October 16.00 UT to 1 October 23.00 UT. If other sources exist in this region we would be overestimating the background flux and thus underestimating the Crab flux. As our upper limits for other sources is based on this background we would also be overestimating our upper limits for the other sources.

An 8σ increase in count rate is observed in the $10\text{--}20^\circ$ plot and increases of 10σ and 8σ in the $20\text{--}30^\circ$ plot as the Crab transits the zenith meridian.

Fig. 1 Counts per 0.5 h versus LT and UT over the flight for γ -ray energies of 1.2–10 MeV and zenith angles of sources of $10\text{--}20^\circ$ and $20\text{--}30^\circ$. Locations of certain possible sources are indicated by arrows. The contours are the shapes of the γ -ray count rate distributions expected from point sources.

The centre and shape of the combined time distribution of the 10–20° and 20–30° data correlate to the counting rate contour expected from the Crab to within 2 degree of arc, with a 1σ uncertainty of 3 degree of arc. This eliminates the SAS 2 source, 195+4 and the two COS B sources in the anti-galactic centre direction, CG176–7 and CG189+1, as the origin of the γ rays.

The telescope, with its finite angular resolution, gives a distribution of zenith angles for a point source. The flux in the observation angle rings of 10–20° and 20–30° is calculated at any desired time and the flux missed from outside these rings is estimated and added. For the Crab, at the time of nearest approach, 9°, at the centre of the contours, the flux from 1.2 to 10 MeV is $3.9 \pm 2.0 \times 10^{-3}$ photons $\text{cm}^{-2} \text{s}^{-1}$.

The energy distribution is determined from plots similar to those in Fig. 1 and plotted in Fig. 2 for the energy intervals of 1.2–3, 3–5, 5–10 and 10–20 MeV. The point at 10–20 MeV gives an upper limit only. Our values are only slightly higher than and compatible with the extrapolations of Walraven *et al.*⁴ and Laros *et al.*⁵ from X-rays to γ -ray energies, as are the recent values of Penningsfeld *et al.*⁶. Our fluxes are about 0.4 of the values of Wilson *et al.*¹¹ measured with the same telescope in 1976 and 0.7 of the preliminary fluxes from this data reported in Kyoto¹. The differences, outside of statistics, arise mostly from the methods of background assignment. Our current values are considered most reliable.

Fig. 2 The energy distribution of X rays and γ rays from the Crab. \blacktriangledown , This experiment; \square , ref. 6; \circ , ref. 11; \triangle , ref. 8; \square , ref. 12; \bullet , ref. 4; \downarrow , ref. 9; \diamond , ref. 7; \uparrow , ref. 10; refs 13, 14, \square , fit of Walraven *et al.*; $---$, fit of Laros *et al.*⁵.

NGC4151 crossed within 8° of the zenith at two times separated by 24 h. There is no evidence in our data from the 10–20° or 20–30° angle intervals for an excess flux at either time. For fluxes from NGC4151 2σ upper limits have been calculated from the background counting rate and are plotted in Fig. 3. These upper limits are factors of 5–10 below the fluxes reported by di Cocco *et al.*¹⁵, Graml *et al.*¹⁶ and Perotti *et al.*¹⁷. The results of Graml *et al.*¹⁶ were withdrawn at the 16th International Cosmic Ray Conference in Kyoto, August 1979, and were replaced by upper limits of 14, 5.5, 2.6 and 0.46×10^{-4} photons $\text{cm}^{-2} \text{s}^{-1} \text{MeV}^{-1}$ at energies of 1.1–2, 2–4, 4–6 and 6–20 MeV, respectively (V. Schönfelder, personal communication). Meegan and Haymes¹⁸ also recently published upper limits for NGC4151. Unless NGC4151 is varying widely in time, by factors of 5–10, our values are in direct conflict with

the above reported fluxes^{15,17} that would have given peaks on Fig. 3 twice as high as the Crab maxima.

As a consequence of our low upper limits and the other upper limits of Fig. 3, the suggestion by Schönfelder²⁶ that the diffuse cosmic γ radiation is the result of superposition of many unresolved galaxies such as the Seyfert galaxy NGC4151 seems premature. There is no observed break in the energy distribution of NGC4151 at 3 MeV and no reason to connect the Seyfert galaxies to the cosmic diffuse γ -ray energy distribution.

Fig. 3 The energy distribution of X rays and γ rays from NGC4151. \blacktriangle , This experiment; \times , refs 21, 22; \square , ref. 23; \diamond , ref. 20; \diamond , ref. 25; \bullet , ref. 19; $+$, ref. 24; \square , ref. 18; \circ , ref. 16; ∇ , ref. 17; \blacksquare , F. Graml *et al.* personal communication.

Although Cyg X-1 and Cyg X-3 passed nearly overhead no evidence for either is seen in Fig. 1. The 2σ upper limits are the same as for NGC4151: 3, 2, 0.6 and 0.4×10^{-4} photons $\text{cm}^{-2} \text{s}^{-1} \text{MeV}^{-1}$ for the energy intervals 1.2–3, 3–5, 5–10 and 10–20 MeV, respectively. For Cyg X-1 our upper limits are a factor of 50 below the fluxes of Baker *et al.*¹² from 1.2 to 10 MeV. Our upper limit from 1.2 to 3 MeV is at the lower limit of the value of Mandrou *et al.*^{13,14}. The fluxes from Cyg X-1 reported by Baker *et al.*¹² would show up on Fig. 1 as peaks 10 times our Crab maxima. It seems that an unusually high time variation, much greater than observed at lower energies (see, for example, ref. 27) would be required to explain the widely varying results of the different observations.

γ -Ray count rates 5σ above background for energies >150 keV were recently reported from the nearest QSO, CG135+1 (ref. 28); however, no absolute fluxes were given. During our flight CG135+1 transited at a minimum zenith angle of 30.3° and its zenith angle was $<35^\circ$ for 4 h. Somewhat less than half of the count rate is expected in the 10–20° and 20–30° angle intervals. Figure 1 shows no excess γ -ray flux from 1.2 to 10 MeV during this time. Using the same procedure as for the other sources, 2σ upper limits of 5, 3, 1.0 and 0.4×10^{-4} photons $\text{cm}^{-2} \text{s}^{-1} \text{MeV}^{-1}$ at energies of 1.2–3, 3–5, 5–10 and 10–20 MeV are obtained for CG135+1.

γ -Rays of 50–500 MeV from the second nearest QSO, 3C273, were reported from COS B observations²⁹, but no fluxes

have been measured at energies of 1–20 MeV. During our flight, 3C273 twice transited at a minimum zenith angle of 28.8° and was at zenith angles less than 35° for 3 h each time. No excess is seen in Fig. 1 on either transit. We find the same 2σ upper limits for 3C273 as for CG135+1.

We thank NASA for the balloon and helium gas and NASA and NSF for support, also the National Scientific Balloon Facility for the balloon launch, flight and recovery.

Multi-ion complexes in the stratosphere—implications for trace gases and aerosol

F. Arnold

Max-Planck-Institut für Kernphysik, 6900 Heidelberg, Postfach 103980, FRG

The fate of stratospheric ions was, until recently, thought to be spontaneous neutralisation following mutual recombination of oppositely charged species. According to Ferguson^{1–3} this need not necessarily apply for sufficiently complex cluster ions, as clustering may stabilise ions against neutralisation. Thus, if neutralisation does not occur, stable ion pairs may be formed. This possibility seemed more likely after the first simultaneous composition measurements of stratospheric positive and negative ions^{4–6} revealed the presence of species more stable than those predicted on theoretical grounds; this led to consideration of a possible role of ion pairs in aerosol formation⁷. Here the formation of ion pairs is investigated in the light of new stratospheric ion composition data. Interactions of ion pairs with other stratospheric constituents, and their significance for aerosol and trace gases is discussed and an experimental check of the existence of the hypothetical stratospheric ion pairs is suggested.

First I consider which ion species among those observed in the stratosphere (positive and negative ions were measured simultaneously around an altitude of 36 km) satisfy the requirements

for stable ion pair formation which is

$$E_D > E_N + E_C \quad (1)$$

Here E_D is the effective energy required to detach the electron from the negative cluster ion, E_N is the effective energy released on neutralisation of the positive cluster ion by a free electron and E_C is the energy released on formation of a chemical bond possibly formed on interaction of core ions or ligands. E_D and E_N are related to the electron affinity E_A of the negative ion core and the ionisation potential IP of the positive ion core by $E_D = E_A + S_-$ and $E_N = IP - S_+$ where S_- and S_+ are the total solvation energies of the negative and the positive cluster ion.

Inspection of the most abundant ions observed around 36 km (Table 1) reveals that the requirement (1) is not fulfilled for the recombination of proton hydrates with NO_3^- (HNO_3)₂, as an E_C of 4.5 eV corresponding to an H–HNO₃ bond⁸ which probably forms has to be considered. Recombination of the observed proton hydrates with HSO_4^- (HNO_3)₂ probably also leads to spontaneous neutralisation as E_D should not be sufficiently large to compensate for the energy E_C corresponding to an H–HSO₄ bond being 4.5 eV (ref. 9). Thus, recombination of the observed proton hydrate ions does not apparently lead to stable ion pairs. Whether or not the observed ions containing the core HX^+ may form stable ion pairs depends on the proton affinity P_A of the as yet not safely identified molecule X. If, as suggested by Ferguson², X was indeed NaOH due to the extremely high P_A of this molecule the HX^+ ions should form stable ion pairs. If, however, X was another molecule having a considerably lower P_A than NaOH only a fraction of the HX^+ -ion recombination may lead to stable ion pairs, depending on the corresponding E_D and E_N and $PA(X)$, although exceeding $PA(\text{H}_2\text{O})$ (ref. 4), may be too low to allow for stable ion pair formation from the observed HX^+ ions.

Note that recombination of more complex cluster ions which have small abundances around 36 km, but which may be even dominant at lower heights should lead to stable pairs even if proton hydrate ions are involved.

In the hypothetical formation of ion pairs, which may be accompanied by loss of some ligand molecules, a stable ion pair interacts with gas molecules. Such interactions may give rise not only to new ligands, but also to a change of core ions. Moreover, due to its large dipole moment the ion pair attaches a free ion quite efficiently. Thus, a three-ion complex may be formed which due to its net charge rapidly attaches an oppositely charged free ion and may form the four-ion complex. Further attachment of free ions may lead to larger multi-ion complexes (MIC) that have the nature of ion crystals or salt particles. An alternative growth mechanism for MIC may be mutual coalescence. Attachment of MIC to pre-existing aerosol particles may also be considered. MIC formation and growth may represent a gas-to-particle formation mechanism which does not require condensation and consequently does not require a supersaturated gaseous species. If, however, a supersaturated species exists, such as sulphuric acid, MIC which have grown to sufficiently large sizes may act as condensation nuclei. The latter have critical sizes which depend on the supersaturation ratio and thus on the abundance of the condensable species and on the temperature. MIC may, therefore, represent a new and interesting class of stratospheric condensation nuclei which had been thought to be mostly of tropospheric and extraterrestrial origin¹⁰. An *in situ* formation of stratospheric condensation nuclei, particularly one initiated by ions was considered to be inefficient^{2,11}. In contrast to the classical mechanism for ion-induced nucleation which requires individual cluster ions to grow to critical sizes and which is inefficient in the stratosphere mainly because there is no gas which is sufficiently supersaturated and is abundant enough to allow for a rapid growth of ions before these recombine. The MIC mechanism avoids this problem by forming condensation nuclei by coalescence of subcritically sized cluster ions. Apart from its possible influence

Table 1 The most abundant positive and negative ions measured around 36 km altitude^{6,16} with their fractional abundances

Positive ion	Abundance (%)	E_N (eV)	Negative ion	Abundance (%)	E_D (eV)
$H^+(H_2O)_4$	21.3	4.03	$NO_3^-(HNO_3)_2$	65.6	5.86
$H^+(H_2O)_5$	17.8	3.38	$HSO_4^-(HNO_3)_2$	14.2	>6.45
$Na^+(H_2O)_4$	19.3	1.92			
$HX^+X(H_2O)_2$	10.7	(<2.53)			
$HX^+X(H_2O)_3$	16.0	(<1.92)			

Values for E_N and E_D are based on measured^{3,17} and estimated cluster ion bond energies. It was assumed that X is NaOH and that NaOH bonds to Na^+ at least as strongly as H_2O and that HNO_3 bonds to HSO_4^- at least as strongly as it bonds to NO_3^- . A measured lower limit to the electron affinity of HSO_4^- (4.5 eV) (ref. 7) was taken. The electron affinity of NO_3^- was taken as 3.9 eV (ref. 18).

on aerosol formation MIC may also have an impact on stratospheric trace gases which may not only condense but also undergo reactions on MIC surfaces. Trace gases which react with, or attach to, these ions may be irreversibly removed from the stratosphere when ions become incorporated into MIC and sediment out of the stratosphere. One example may be sulphuric acid which was found to have a very low gas phase abundance in the stratosphere and which was suspected to be removed by ion processes¹².

If aerosol formation through MIC were significant, it would provide a link between solar activity which controls the stratospheric and tropospheric ionisation sources (galactic and solar cosmic radiation) and stratospheric and possibly also upper tropospheric aerosol. According to Dickinson¹³ such a link seems to be the most favourable way of connecting the Earth's climate to solar activity.

The volume rate R_V at which gas is converted into aerosol by the MIC process is $R_V = \alpha n^2 AM$. Here, α , n and M are the ion-ion recombination coefficient, the total number densities for free positive and negative ions and the average mass of an ion pair, respectively. The parameter A which ranges between 0 and 1 describes the fraction of recombinations which lead to stable ion pairs. Assuming X to be NaOH A becomes 0.5 at 36 km and thus M becomes 4.7×10^{-22} g if α and n are taken as 10^{-7} cm³ s⁻¹ and 2,000 cm⁻³ (ref. 6). For the evaluation of M it was assumed that the mass of an ion pair equals the sum of the masses of the two free cluster ions which mutually recombine. Thus, R_V becomes 1.2×10^{-22} g cm⁻³ s⁻¹. Integration of R_V over the height interval 55–33 km where 'non proton hydrates' have been observed^{4,6} yields a column rate for gas to particle conversion $R_C = 6.3 \times 10^{-17}$ g cm⁻² s⁻¹. Here A was taken to be equal to the fractional abundance of 'non-proton hydrates'⁴ and n_+ and n_- were computed from a mid latitude galactic cosmic ray ionisation rate considering α -values as given by Smith and Church¹⁴. When compared with the column rate for gas-to-particle conversion required to account for the observed stratospheric aerosol layer which is estimated to be about 1.1×10^{-15} g cm⁻² s⁻¹ (ref. 15) the above value is much smaller.

Thus, MIC formation and growth in the upper stratosphere followed by sedimentation of larger MIC into the region of the main aerosol layer apparently cannot account for the total aerosol mass observed in this layer. If, however, at heights below 33 km all ions had the potential to form stable ion pairs ($A = 1$), the MIC process may even account for a large fraction of the total aerosol mass observed.

To estimate MIC abundances it is assumed that ion pairs (2-IC) are formed by mutual recombination and are lost by free ion attachment (rate constant k assumed to be of the order of 10^{-9} cm³ s⁻¹—the upper limit for an ion molecule reaction) to aerosol particles (time constant τ ; a sticking coefficient of 1 is assumed) a steady state treatment yields

$$n_2 = \frac{A \alpha n^2}{k 2n + \tau^{-1}} \quad (2)$$

and

$$n_3^+ = A n \left(2 + \frac{1}{k n \tau} \right)^{-1} \quad (3)$$

where n_2 and n_3 are the total number densities of 2-IC and positive 3-IC. Neglecting aerosol interaction for an altitude around 35 km ($A = 0.5$, $n = 2,000$ cm⁻³ and $\alpha = 10^{-7}$ cm³ s⁻¹) n_2 and n_3^+ become 5×10^4 cm⁻³ and 5×10^2 cm⁻³. Analogous steady state considerations lead to $n_4 = 5 \times 10^4$ cm⁻³ and $n_5^+ = 5 \times 10^2$ cm⁻³. A more realistic estimate including aerosol interaction with $\tau = 10^5$ s (ref. 12) yields $n_2 = 5 \times 10^4$ cm⁻³, $n_3^+ = 1.3 \times 10^2$ cm⁻³, $n_4 = 2.9 \times 10^1$ cm⁻³ and $n_5^+ = 2.9 \times 10^{-1}$ cm⁻³. For negatively charged MIC the number densities should be the same as for positive ones. Thus, for the more realistic case, charged MIC apparently contribute a few per cent to the total concentration of charged particles. Also, the abundance of charged MIC apparently decreases steeply with increasing number of ions contained in these complexes. The estimates, however, depend sensitively on τ and thereby on the surface area density of the aerosol, the value of which is somewhat uncertain.

The present detection limit of balloon-borne ion mass spectrometers is ~ 1 particle cm⁻³ for both positively and negatively charged species. When compared with its value, the above estimate of $n_3^+ = n_3^-$ is much larger and, consequently, charged MIC should be detectable even if several individual species of 3-IC are present, and their partial number densities are therefore, considerably smaller than their total number density. Previous instruments were probably not suitable for detection of charged MIC due to their low mass ranges.

Therefore, I suggest a search for stratospheric charged MIC, using ion mass spectrometers with greatly increased mass range. This may provide information relevant to stratospheric aerosol- and trace-gas processes and may be the most promising way of obtaining experimental information about the hypothetical MIC that are difficult to study in the laboratory.

I thank E. Ferguson for helpful discussions.

Jointed blocks of peridotite xenoliths in basalts and mantle dynamics

Asish R. Basu

Department of Geological Sciences, University of Rochester,
Rochester, New York 14627

In considering the formation of fracture in the upper mantle of the Earth, several authors^{1,2} have pointed out that the major problem in the formation of cracks is the fact that tensile stresses in the upper mantle region, particularly in the lithospheric plate, are too small compared with the hydrostatic overburden pressure. From theoretical considerations, Anderson² demonstrated that cracks can nucleate in the lithospheric plates by the accumulation of low density fluid at the base of the plate in the presence of tensile stresses parallel to the plate surface. However, there has been no direct geological observation that supports this conclusion. This letter reports geological observations of planar features in ultramafic inclusions which may have important implications on the existence of fracture in an ambient upper mantle condition.

Ultramafic inclusions in alkalic and related basalts provide much information about the Earth's upper mantle. These inclusions, mostly spinel and garnet peridotites, are considered to be the broken pieces of the wall rocks of the volcanic conduits. In this way, these rocks are the natural 'drill-hole' samples of the upper mantle and may come from depths of up to 200 km (refs 3, 4). Numerous aspects of these rocks have been studied, including the major and minor element chemistry, the isotopic chemistry, the general petrology and petrography, and the rheological properties, to understand the composition and evolution of the upper mantle. However, very little is known about the process by which these inclusions are torn off the walls of the volcanic conduits. The process apparently indicates brittle failure in the mantle in the immediate vicinity of hot magma where the temperatures, in contrast, are appropriate for plastic behaviour.

During petrologic investigation of the ultramafic xenoliths in basalts from San Quintin, Baja California⁵, I observed that many of the xenoliths show angular to subangular shapes resulting from more than one bounding planar surfaces. In some xenoliths three orthogonal sets of such planar surfaces can be recognised. Wilshire and Trask⁶ also recognised similar features in xenoliths from Dish Hill, California. Therefore, planar surfaces in xenoliths in basalts may be common but generally disregarded.

Figure 1 shows a spinel lherzolite xenolith from San Quintin with planar features. The xenolith has a tabular shape, with one perfectly flat surface which measures 25 cm diagonally. Approximately 4 cm away from this surface is another planar feature—a joint plane—that cuts across the massive xenolith. All the bounding surfaces of the xenolith are covered by the frothy, alkalic basalt. As the joint plane does not cut across the host lava, it must have formed before the consolidation of the latter. This observation also suggests that the commonly observed angular to subangular xenoliths result from the formation of sets of joint planes in the upper mantle before invasion by the basalts that carried the xenoliths to the surface. Once the xenoliths are included in this basalt, they are brought up to the surface relatively rapidly by the host basalt as discussed in the following section.

The maximum time spent by the xenoliths in host basalts during the ascent of the magma can be estimated by using Stokes' Law, which states that

$$V_s = \frac{2\Delta\rho ga^2}{9\eta}$$

where V_s is the velocity of settling of a spherical solid of radius a ; $\Delta\rho$, the difference in density between the solid and the fluid; η , the viscosity of the fluid; and g the acceleration due to gravity. Using $a = 15$ cm, the radius of the largest xenolith found in San Quintin, $\Delta\rho = 0.6$ (density of xenolith 3.3 g cm^{-3} and that of basaltic glass 2.7 g cm^{-3}) and $\eta = 10^3 \text{ P}$ for alkalic basalt, we obtain $V_s = 30 \text{ cm s}^{-1}$. Therefore, in a static alkali basaltic magma chamber the xenoliths will settle with as high a velocity as 30 cm s^{-1} . For the magmas to ascend to the surface containing the xenoliths, they must ascend with a velocity $> 30 \text{ cm s}^{-1}$. The depths from which the xenoliths come may be as deep as 75 km. Therefore, with a velocity of ascent of 30 cm s^{-1} , the basalt will take 70 h or ~ 3 days to arrive at the surface from a depth of 75 km. As 30 cm s^{-1} is the minimum velocity ascribed to the ascending magma, 3 days is the maximum time the magma takes to arrive at the surface. Therefore, the xenoliths could not have spent more than 3 days in the ascending basalt. An important parameter in the above estimate is the viscosity of alkali basalt taken as 10^3 P . Recent experimental determination⁷ of this parameter suggests that 10^3 P may be higher than the actual viscosity measured under high pressure. In that case, the mean residence time of xenoliths in liquid basalt must be < 3 days. This determination of the relatively short residence time of xenoliths in their host basalts is important because it justifies the interpretation of the chemistry, mineralogy, texture and structure of the xenoliths as representative of an equilibrium condition in the upper mantle.

Fig. 1 A jointed block of spinel lherzolite inclusion in alkalic basalt showing a penetrative joint plane parallel to the black marker line. The block of lherzolite is surrounded on all sides by the frothy, scoreaceous basalt that brought up the inclusion to the surface.

There are two possible interpretations for the origin of the joint planes in the xenoliths. First, they could have formed because of the sudden release of lithostatic pressure during the rapid transport to the surface. If that is true, then the joint planes must represent pre-existing planes of weakness. Second, the joints formed by brittle failure in the upper mantle before the xenolith's incorporation by the magma. Note in this connection the mode of occurrence of amphibole selvages on flat surfaces in some xenoliths from Dish Hill, California⁶. The occurrence of amphibole selvages on flat surfaces of these peridotites may indicate that they formed as veins along joint planes in upper mantle conditions.

Is it possible for joint planes to develop under high lithostatic pressure in the upper mantle? It is well known that the presence

of fluid within a massive body of rock reduces the strength of the rock^{8,9}. In effect, the fluid pressure reduces the load pressure, thereby reducing the strength of the rock⁸. This principle has been applied to the effective decrease in strength of a rock due to the generation of magma and to the process of crack propagation by magma in the brittle failure region¹¹. The field of brittle fracture is expanded by fluid pressure because the pressure of the fluid in pores and cracks counteracts the normal stress across the cracks from lithostatic pressure. However, there is no apparent evidence for the presence of fluid magma or volatiles along the joint plane of the lherzolite xenolith under discussion. In the absence of the evidence of such fluid phases along the joint plane, the alternative and most viable explanation for the origin of the joint planes is that they formed under high differential stress of the order of several kilobars.

Analysis of stresses in ultramafic xenoliths showing varying degrees of plastic deformation indicate a range of 250 to 700 bar and analyses of upper mantle strain rates show that rates of 10^{-15} to 10^{-13} s^{-1} are typical for plastically deformed mantle as represented by ultramafic xenoliths¹². However, the joint planes in the xenolith under discussion must have formed at much higher stresses and the corresponding strain rates must be significantly higher than 10^{-13} s^{-1} .

An argument can be made against the interpretation that the joint planes in the xenolith formed due to the release of lithostatic pressure. During the transport of the xenoliths to the surface from mantle depths, two competing processes will operate: decompression due to pressure release and the contraction due to fall in temperature. The anisotropy of olivine, the major constituent of the xenoliths, is of the order of 5% (ref. 13). Thus, the low differential compressibility of olivine in the xenolith is expected to be manifest in the scale of the individual grains. The net effect of these processes can be observed in the mineral grains of many xenoliths which become uncompact due, possibly, to this differential compressibility. The scale of the observed joint planes (several centimetres) in the xenolith (Fig. 1) indicate then the presence of directed stress of at least a similar scale.

Therefore, it is possible that the joint plane (Fig. 1) in the lherzolite xenolith formed in the upper mantle by brittle failure; some intermediate focus earthquakes such as those in Hawaii¹⁴ may indicate this brittle behaviour. When the alkalic magma rises from below, it picks up the jointed blocks of the mantle and brings them to the surface relatively rapidly. In this way, the jointed blocks of the xenoliths will still preserve the ambient properties of the upper mantle, such as high P , T conditions of mineralogical equilibria and evidence of plastic flow.

The most probable explanation for the origin of the joint plane in the lherzolite (in Fig. 1) is that it formed because of high differential stress in the upper mantle. The commonly observed angular to subangular shapes of mantle-derived xenoliths in alkali basalt reflect this phenomenon, and provide a mechanism for these mantle rocks to be torn off the walls of the volcanic conduits.

Uppermost Miocene carbon isotope stratigraphy of a piston core in the equatorial Pacific

L. D. Keigwin Jr

Graduate School of Oceanography, University of Rhode Island, Kingston, Rhode Island 02881

N. J. Shackleton

Godwin Laboratory, Freeschool Lane, Cambridge, UK

Carbon isotopic analyses of benthonic foraminifera from palaeomagnetically dated piston core RC12-66 (east equatorial Pacific Ocean) show a permanent decrease in $\delta^{13}\text{C}$ of $\sim 0.5\%$ in the upper reversed interval of palaeomagnetic Epoch 6 (about 6.3 Myr BP). Magnetostratigraphic and biostratigraphic correlations reported here suggest that this decrease is isochronous with a similar carbon shift observed at localities elsewhere in the Indo-Pacific region.

A permanent decrease of $\sim 0.5\text{--}0.8\%$ in the $\delta^{13}\text{C}$ of benthonic foraminiferal calcite has been reported from the Pacific¹⁻⁴ and Indian Oceans⁵ during the late Miocene. These studies are part of the CENOP (Cenozoic Palaeoceanography) programme which is seeking to define isochronous markers for palaeoceanographic reconstructions⁶. This shift in $\delta^{13}\text{C}$ has been interpreted as an oceanwide change in the metabolic CO_2 content of deep waters, resulting from a change in circulation and upwelling patterns, from increased supply of organic matter to the deep sea due to a late Miocene regression, and from a change in ocean fertility^{2,5,7}. Palaeomagnetic dating of this event at an uplifted shallow-marine sequence (Blind River) in New

Fig. 1 Carbon isotopic results (‰, PDB), magnetostratigraphy¹⁰, and biostratigraphy¹¹ of the latest Miocene at core RC12-66.

Zealand places it at ~6.2 Myr, within palaeomagnetic Epoch 6 (refs. 3, 8, 9). It has still not been proved that the late Miocene carbon shift represents an isochronous event because it has been palaeomagnetically dated only at the Blind River section. From biostratigraphic evidence, however, the late Miocene carbon shift was assigned ages of ~6.5 Myr (ref. 1) and ~6.2 Myr (ref. 5).

We have found the carbon shift in east Equatorial Pacific Ocean piston core RC12-66. Core RC12-66 (02°36.6' N, 148°12.8' W, 4755m) is one of the longest piston cores recovered from the deep ocean (28 m). This core has been the subject of detailed magnetostratigraphic¹⁰ and biostratigraphic studies^{11,12}. Magnetic plug samples (of ~5 cm³) originally studied by Foster and Opdyke¹⁰ were provided by L. H. Burckle of Lamont-Doherty Geological Observatory. The samples were washed and specimens of the benthonic foraminifer *Globocassidulina subglobosa* were picked from the size fraction greater than 175 µm and analysed using standard procedures¹³.

Carbon isotopic results (Table 1), expressed as $\delta^{13}\text{C}$ with respect to the standard PDB, decrease upwards by about 0.5‰ between ~2,450 and 2,600 cm (Fig. 1). There is unexplained high frequency variability of as much as 0.6‰, but on average the shift seems permanent. Pliocene and Pleistocene $\delta^{13}\text{C}$ results from nearby piston core V28-179 (ref. 14) are on average lighter than the lowest results at RC12-66. Likewise, other sections in the Indo-Pacific show that this is indeed a permanent change.

The age that is applied to the 1.5-m interval over which the shift occurs depends on the age assignment of the palaeomagnetic boundaries of magnetic Epoch 6. Both this study and that of Loutit and Kennett use a new time scale from the Gilbert/Gauss boundary to the inferred base of Epoch 6 based on direct dating of subaerially erupted lavas in Iceland¹⁵. Ages for the boundaries of Epoch 6 given by McDougall *et al.*¹⁵ and corrected in accordance with Mankinen and Dalrymple¹⁶ are ~5.98 and 6.71 Myr. Using this time scale, which is probably the most accurate for magnetic Epoch 6, we estimate the age of the late Miocene carbon shift to be ~6.3 Myr. The corrected time scale of McDougall *et al.*¹⁵ indicates an age of ~6.2 Myr for the carbon shift in the Blind River section³, in good agreement with that for RC12-66. Magnetostratigraphy, therefore, suggests that the carbon shift is isochronous between the south-west Pacific land-based sequence and the east equatorial Pacific Ocean.

Biostratigraphy also suggests the carbon shift is an isochronous marker in deep-sea sequences. At RC12-66 the carbon shift interval is marked by the evolution of the radiolarian *Stichocorys peregrina* from *Stichocorys delmontensis*¹¹. Just above this level there is an interval of sinistral *Neoglobobulimina acostaensis*, followed by the first appearance of *Pulleniatina primalis*. This is the same sequence of events found at DSDP 158 (ref. 1). In addition, where nanofossil biostratigraphy has been examined, it is found that the carbon shift is associated with the first appearance of *Ammaurolithus primus*¹⁷.

At DSDP Site 158 the carbon shift was originally reported to occur within a 3-m interval¹, but subsequent more detailed studies by one of us (L.D.K.) reveal that it is restricted to only a 1-m interval. The sedimentation rate through this interval is estimated to be ~50m Myr⁻¹ (ref. 18), and thus the carbon shift seems to have occurred in ~50,000 yr. In the New Zealand Blind River section an upper limit on the duration of the shift is 150,000 yr. (ref. 3). At RC12-66 we estimate from the magnetostratigraphy of Foster and Opdyke¹⁰, that the late Miocene sedimentation rate is ~8m Myr⁻¹. This rate provides a duration of this event of ~200,000 yr at RC12-66. Further studies of high sedimentation rate cores are necessary to establish the minimum duration of this event.

We thank J. P. Kennett and T. S. Loutit and E. Vincent for comments. L. D. K. was supported by NSF grant OCE 76-81489 (CENOP).

North Atlantic oceanography as possible cause of Antarctic glaciation and eutrophication

Detmar Schnitker

Department of Oceanography, University of Maine at Orono, Walpole, Maine 04573

Tarling¹ suggested that ice ages may occur when continental blocks occupy polar positions, isolating the pole from oceanic influences, and when nearby seas are available to provide moisture for the build-up and maintenance of polar ice caps. Such conditions gradually became established in the Southern Hemisphere where the present ice age began 13 Myr ago². The Cenozoic circum-Antarctic geographic and oceanographic evolution has been recently summarised by Kennett³. I report here that circum-Antarctic palaeogeography and palaeoceanography alone were insufficient to lead to the Antarctic glaciation. A model is presented that suggests that the final triggering events took place in the North Atlantic.

Formation of the Atlantic and Indian oceans during the Cretaceous and the early Cenozoic left Antarctica and Australia in a polar position⁴. Separation of Australia from Antarctica during the late Eocene opened a seaway in which an almost continuous circum-Antarctic current system could form, which in turn effectively isolated the Antarctic continent⁵. Concomitant with, and perhaps caused by this change of ocean configuration was a decrease of global warmth from a mid-Cretaceous high⁶, so that by late Eocene/earliest Oligocene time freezing temperatures prevailed along Antarctic coasts⁷. Although the southern ocean has probably been the principal source of the world oceans' deep and bottom water since at least the late Cretaceous⁸, the formation of Antarctic bottom water at freezing temperatures near the Eocene/Oligocene boundary stimulated the oceans' deep water circulation as manifested by widespread erosional hiatuses⁹, a drastic drop of the carbonate compensation depth^{10,11}, and a reorganisation of benthic deep water faunas^{12,13}. During the remainder of the Palaeogene Antarctica remained a cold but largely ice-free continent.

Zonal winds (polar easterlies, prevailing westerlies), driven by the newly established thermal contrast, set up zonal ocean currents. After opening of the Drake passage near the Oligocene/Miocene boundary, ~22.5 Myr ago¹⁴, a fully circum-Antarctic current formed. The Ekman drift that resulted from these zonal wind fields caused upwelling around Antarctica. This upwelling, however, could have brought up only cold water of low salinity from shallow (~100 m) depth (A. L. Gordon, personal communication). A probable consequence of this upwelling and of the interaction of the vigorous currents with bottom and coastal features is a zone of high biological productivity, noted to have occurred from the late Eocene onward, in proximity to the Antarctic continent¹⁵⁻¹⁷. But in general, the southern ocean remained an oligotrophic region of general downwelling, dominated by calcareous floras and faunas. The great transition to essentially modern conditions, that is Antarctic continental glaciation and circum-Antarctic oceanic eutrophication, occurred during the early and middle Miocene. These events have no apparent 'cause' in any Southern Hemisphere tectonic or oceanographic event, but seem to correlate well with two tectonic events in the Northern Hemisphere that fundamentally rearranged the North Atlantic circulation system: (1) the closure of the Mediterranean at its eastern end, and (2) the subsidence of the Iceland ridge (Greenland-Iceland-Faeroe ridge).

Closure of the eastern Mediterranean during the early Miocene was completed ~18 Myr ago¹⁸, interrupting the circum-

Fig. 1 General current system of the Atlantic Ocean. *a*, Pre-Miocene, with emergent Iceland ridge. *b*, Post-mid-Miocene, with submerged Iceland ridge and Norwegian Sea overflow.

global, near-equatorial flow through Tethys. The resulting sea, lying at or below 30° N latitude⁴, became an evaporation basin which must have contributed increasing amounts of warm and very saline water to the North Atlantic⁸. During the early Miocene the Atlantic probably became, as it still is today, the saltiest of all oceans.

Since seafloor spreading between Greenland and Europe began, ~53 Myr ago, the aseismic Iceland ridge had been an effective barrier between the Atlantic ocean and the north polar sea. During the latest Oligocene, ~25 Myr ago, the first segments of the Iceland ridge began to subside below sea level^{19,20}. This initial subsidence allowed ingress of North Atlantic surface water into the then already cold Norwegian sea²¹, but the barrier was probably still too shallow to allow return flow of deep water into the North Atlantic. By the mid-Miocene, subsidence of the Iceland ridge had progressed to such depths that reflux of cold deep water became significant, thus linking the north polar sea as a heat sink to the world ocean. The establishment of the North Atlantic as a major source of deep water for the world ocean brought about a fundamental rearrangement of the global deep-water circulation.

The early Norwegian Sea overflow water, formed through cooling of North Atlantic water, might not have been very cold, having achieved sufficient density for sinking and outflow as a result of its high salinity which it inherited from the Mediterranean outflow. The outflow of this early Norwegian Sea overflow water soon reached great proportions, causing major sediment redistribution within the North and South Atlantic ocean²²⁻²⁴.

The early North Atlantic deep water which resulted from the Norwegian Sea overflow water, like its modern counterpart, travelled the length of the Atlantic Ocean and inserted itself from below as an intermediate water mass into the circum-Antarctic system. The arrival of this North Atlantic deep water destabilised the vertical structure of the circum-Antarctic system so that the existing wind-induced belt of upwelling could bring North Atlantic deep water to the surface instead of the cold, low salinity local water from shallow depths (A. L. Gordon, personal communication). The upwelling water was nutrient-rich and led to the transformation of an oligotrophic area to one of high biological productivity, which has characterised Antarctic waters until today.

The great volume of relatively warm but saline North Atlantic deep water that was thus injected into the cold circum-Antarctic environment contained heat that could be converted to latent heat by evaporation. The ensuing high evaporation rates supplied much moisture to the Antarctic continent, which had been 'precooled' to below freezing temperatures for nearly 25 Myr, since the late Eocene. Retention of this moisture on Antarctica formed and maintained the continental ice cap. This

sudden build-up of the Antarctic ice cap as soon as sufficient moisture became available suggests that the previous lack of substantial glaciation on Antarctica was probably due to severe dryness rather than moderate temperatures.

Increased thermal contrast in the Antarctic induced stronger, wind fields which led to an enlargement of the upwelling system, as indicated by the progressive northward displacement of the Antarctic convergence³ and also to continued growth of the Antarctic ice sheet, which by the end of the Miocene may have been 50% larger than today²⁵. The eustatic lowering of sea level which accompanied the growth of the Antarctic ice sheet was sufficient to bring about the final separation of the Mediterranean from the Atlantic, the Messinian salinity crisis²⁶. The Mediterranean, therefore, ceased to supply saline water to the North Atlantic. North Atlantic surface water now flowing into the Norwegian-north polar sea required, because of its lessened

salinity, more intensive cooling to achieve sufficient density for sinking and later overflow. The eustatically lowered sea level also shoaled the Iceland ridge and probably caused a reduction of the volume of outflow of this new, colder, and less saline Norwegian Sea overflow water. When this new North Atlantic deep water was brought to the surface by the circum-Antarctic upwelling system it maintained, because of its high nutrient content, the very productive Antarctic siliceous bioprovince, but because of its lower temperature reduced the rates of evaporation from the ocean. Precipitation 'starvation' led to a drastic reduction of the Antarctic ice sheet soon after the Miocene-Pliocene boundary^{27,28}.

I thank Dr A. L. Gordon for explaining important aspects of Antarctic physical oceanography, also Drs J. P. Kennett and T. B. Kellogg for critical reviews, and the NSF for support through grant DES 75-13855.

***In vitro* effects of high molecular weight forms of ACTH on the fetal sheep adrenal**

Margaret M. Roebuck & Colin T. Jones

Nuffield Institute for Medical Research, Headley Way, Oxford OX3 9DS, UK

Diane Holland & Robert Silman

Department of Reproductive Physiology, The Medical College of St Bartholomew's Hospital, London EC1, UK

The direct involvement of the pituitary-adrenal axis in birth has been well established, at least in sheep, and its removal prolongs pregnancy^{1,2}. As part of the process the fetal sheep adrenal grows rapidly during the 10-15 d prepartum and is associated with a large rise in the plasma corticosteroid concentration^{3,4}. This does not seem to result from an increased ACTH secretion^{5,6}. The fetal adrenal *in vivo* seems refractory to circulating ACTH and shows poor response to elevation of plasma concentration^{1,2,7-9}. Thus the signal for the adrenal hypertrophy and the initiation of parturition remains unclear. The responsiveness of the fetal adrenal to ACTH has been re-examined using isolated adrenal cells. The study shows that in the fetal sheep these are not inherently unresponsive to ACTH, but that high-molecular-weight forms of ACTH block the action of ACTH₁₋₃₉. These peptides may be responsible for controlling the activity of the adrenal *in situ*.

To see whether the pathway for ACTH stimulation of steroidogenesis was poorly developed in the fetal sheep adrenal 10-30 d before birth cells were prepared from the gland and incubated *in vitro*. Cells from fetal sheep of 120-135 d were prepared by collagenase digestion^{10,11}. Adrenals were trimmed, weighed, finely chopped with a scalpel blade and suspended in

10 ml of Krebs bicarbonate buffer containing 20 mM-HEPES pH 7.4, 0.5% (w/v) bovine serum albumin and 25 mg of collagenase (Sigma, Type 1) in a 20-ml plastic vial. This was gassed with 95% O₂ and 5% CO₂ at 37 °C for 60 min and the cell suspension stirred with a polytetrafluorethylene paddle rotating at 500 r.p.m. The suspension was filtered through a 100-μm nylon mesh and centrifuged at 200g for 15 min. The cells were washed twice in 10 ml of Krebs bicarbonate buffer containing 0.5 mg ml⁻¹ soya bean trypsin inhibitor (Sigma), then finally suspended in 50 ml of the same buffer containing the trypsin inhibitor. Aliquots of 0.5 ml of this cell suspension were added to 0.1 ml of 50 mM sodium phosphate (pH 7.5) containing a range of ACTH concentrations in 2-ml polystyrene tubes, then incubated under 95% O₂ and 5% CO₂ for 2 h at 37 °C in a shaking water bath. At the end of the incubation the cells were centrifuged at 1,000g for 15 min at 4 °C and the supernatant was used for the assay of cortisol. Details of the collection of plasma samples and of the assay of ACTH and cortisol have been described previously⁷. The ACTH₁₋₃₉ used in these studies was the human standard obtained from the National Institute for Biological Standards and Control, London.

For the preparation of large molecular weight peptides, pituitaries were collected from adult Welsh mountain sheep. They were rapidly frozen in liquid nitrogen and stored at -70 °C. Before chromatography they were thawed and homogenised in 0.02 M-HCl (10 mg in 0.5 ml) with 1 mM disopropylphosphorofluoridate. After centrifugation at 2,500 r.p.m. for 10 min, 0.5-2 ml of the supernatant was run on a 1.6 × 100 cm column of Sephadex G-100 Superfine and eluted with 1 M acetic acid at 1.6 ml per h and 4 °C. Fractions were collected every 15 min. Three large molecular weight peptides A, B and C, which react with anti-ACTH₁₋₂₄, were separated¹². They have approximate molecular weights of 50,000, 30,000 and 20,000 respectively¹². In some cell incubations they were added either in place of ACTH₁₋₃₉ or together with 166 pg ml⁻¹ of ACTH₁₋₃₉.

Previous experiments on the fetal sheep with chronically implanted vascular catheters have shown relatively small changes in corticosteroid concentration for relatively large rises

Table 1 The output of cortisol from adrenal cells of 120–135-d fetal sheep in response to various ACTH concentrations

	0	ACTH concentration (pg ml ⁻¹)			
		40	166	332	1,660
Cortisol produced (ng per 2 h per g of DNA)	0.4 ± 0.16	1.45 ± 0.4	4.35 ± 1.35	5.86 ± 1.64	6.73 ± 1.98
Percentage increase over baseline	—	222%	867%	1,202%	1,396%

The results are means ± s.e.m. of nine experiments.

in ACTH⁷⁻⁹. In contrast to the *in vivo* data, adrenal cells prepared from fetal sheep of 120–135 d gestation respond by causing a marked increase in cortisol output in response to low concentrations of ACTH₁₋₃₉ (Table 1). Note particularly the effect of increasing the concentration from 40 to 330 pg ml⁻¹ and to 1,660 pg ml⁻¹ which represents approximately the basal to the elevated concentration of ACTH₁₋₃₉ in plasma of fetal sheep for experiments carried out *in vivo*⁷⁻⁹. An interpretation of the *in vivo* compared with the *in vitro* data is that *in vivo* something is suppressing the ability of the fetal adrenal to respond to circulating ACTH, although a direct comparison is not easy. This does not appear to be a low PO₂ (unpublished observations). The proportional increase in cortisol output by the fetal adrenal cells between 40 and 330 pg of ACTH per ml,

was of the same order as that found in adrenal cells prepared from the glands of adult guinea pigs, man, rats and sheep¹³⁻¹⁵.

The pituitary of the fetal sheep contains ACTH-like peptides of high molecular weight which are secreted^{12,16} and found in the circulation¹⁷. The proportion of these to ACTH₁₋₃₉ falls in the preparturient period¹⁸. The effects of these peptides on cortisol responses of adrenal cells have shown consistent results in four fetal sheep (Fig. 1). They illustrate that the large peptides (even A, $P < 0.05$) have steroidogenic activity at 1 ng ml⁻¹, but inhibit the response of the ACTH₁₋₃₉ (Fig. 1). It is difficult to exclude the possibility that there is proteolytic breakdown of the large peptides to ACTH₁₋₃₉, as occurs in plasma; were that occurring *in vitro*, it would mask part of the inhibitory action of the three peptides, thus accounting for the impression of the absence of inhibition in some cases.

These three peptides are present in the pituitary of the fetal sheep and are secreted by pituitary cells. The concentration of high-molecular-weight ACTH-like peptides in the plasma (mostly peptides similar to A and B) of fetal sheep at 120–135 d is about 150 pg ml⁻¹ compared with a value of about 50 pg ml⁻¹ for ACTH₁₋₃₉ (ref. 18).

Thus the existence of these peptides in the fetal circulation may explain why the fetal adrenal is apparently less responsive *in vivo* than *in vitro*. Moreover, the change in the ratio of the concentration of these to that of ACTH₁₋₃₉ that occurs late in gestation in the fetal sheep could be involved in the initiation of parturition, possibly by influencing the trophic and steroidogenic effects of ACTH₁₋₃₉ on the adrenal. If these big peptides are suppressing the fetal adrenal of the sheep then they provide an

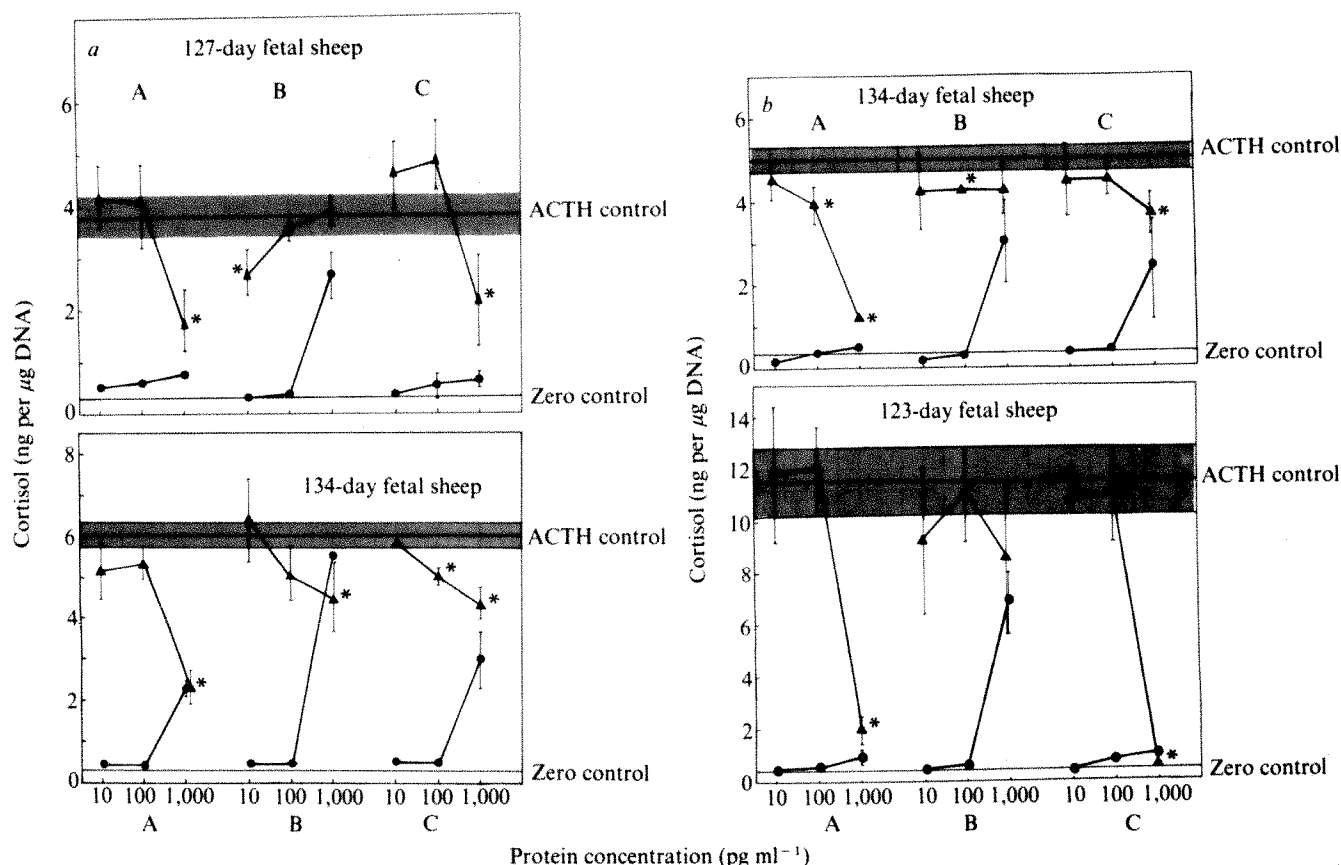

Fig. 1 The response, to ACTH₁₋₃₉ and various ACTH peptides, of adrenal cells prepared from four fetal sheep of 123–134 d gestation. Cells were incubated for 2 h with either 166 pg ml⁻¹ ACTH₁₋₃₉ (ACTH control; the shaded area is equivalent to 2 s.d.), with ACTH₁₋₃₉ plus various concentrations of big peptides (▲), with the big peptide alone (●), or without any addition (zero concentration control). The peptides A, B and C have molecular weights of about 50,000, 30,000 and 20,000, respectively. The values are means ± s.d. for three separate incubations. The rates of cortisol production in the zero controls were 123 d 0.43 ± 0.03, 127 d 0.35 ± 0.07, 134 d 0.39 ± 0.02, 134 d 0.28 ± 0.02 ng of cortisol per 2 h per µg DNA.

* Indicates a significant difference between the response of the cells incubated with ACTH₁₋₃₉ at 100 pg ml⁻¹ as compared with that on incubation with the appropriate peptide plus 100 pg ml⁻¹ of ACTH₁₋₃₉ ($P < 0.05$).

explanation for the paradoxical effect of short-term dexamethasone infusion into the fetal sheep increasing the response to ACTH₁₋₂₄ (ref. 19) as dexamethasone would reduce the secretion of the large peptides as well as that of ACTH₁₋₃₉.

The mechanism by which these large peptides suppress adrenal steroidogenic response to ACTH is not clear. Provided they contain the 15–18 region of the ACTH molecule they should compete effectively for the ACTH receptor and then may block the accessibility of ACTH₁₋₃₉ to the steroidogenic site on the adrenal cell membrane²⁰.

We are grateful to Professor G. S. Dawes for his interest and encouragement. M.M.R. is an MRC Scholar. This study was supported by grants from the MRC and the Wellcome Trust.

Autoregulation in rats with transplanted supernumerary kidneys

Ruben F. Gittes, Marcus Rist, Salvador Treves & Andrew Biewiner

Harvard Program in Urology (Longwood Area), Department of Surgery, Peter Bent Brigham Hospital, and Departments of Radiology, Children's Hospital Medical Center, Harvard Medical School, Boston, Massachusetts 02115

Autoregulation of mammalian renal function is implicit in the fact that a few hours after removal of one kidney the activity of the intact nephrons in the other kidney suddenly increases, both in glomerular filtration and tubular reabsorption. There follows a slower but easily measured increase in renal mass—compensatory hypertrophy in each residual nephron. That response to a reduction of nephrons has been well studied¹, but the adaptation of normal renal function to additional nephrons could not be tested until microsurgical techniques made it possible to transplant one or two additional kidneys into normal rats². We report here sequential measurements of the total renal function of rats with three and four kidneys. Our results indicate that autoregulation maintains total renal function at normal levels in spite of a doubling in the number of nephrons and apparent renal mass.

Strictly inbred Lewis rats were used to avoid immunological reaction against the added tissue and to facilitate long-term observations. As before², the donor kidney (or kidneys) was removed *en bloc* with adjacent segments of aorta and vena cava, as well as with the entire ureter and a small patch of bladder.

Recipients were young adult males, whose aorta and vena cava in mid-abdomen was slit anteriorly and joined by sutures of 9.0 nylon to the cuffs of the donor aorta and vena cava. The urine from the added kidney was drained into the recipient's bladder by sewing the patch of donor bladder, which included the ureteral orifices, into a defect cut into the dome of the bladder with 7.0 Dexon. Thus there was no surgical interference with the blood vessels or ureters of the recipient's own kidneys. Unless the donor kidney is spared from ischaemia during transplantation, the resulting acute tubular necrosis of the transplant is particularly severe and the transplanted kidneys atrophy³. We perfused donor kidneys with ice-cold Ringer solution and performed rapid anastomoses. We discarded rats in which the transplants atrophied, as well as those that developed hydro-nephrosis or bladder stones.

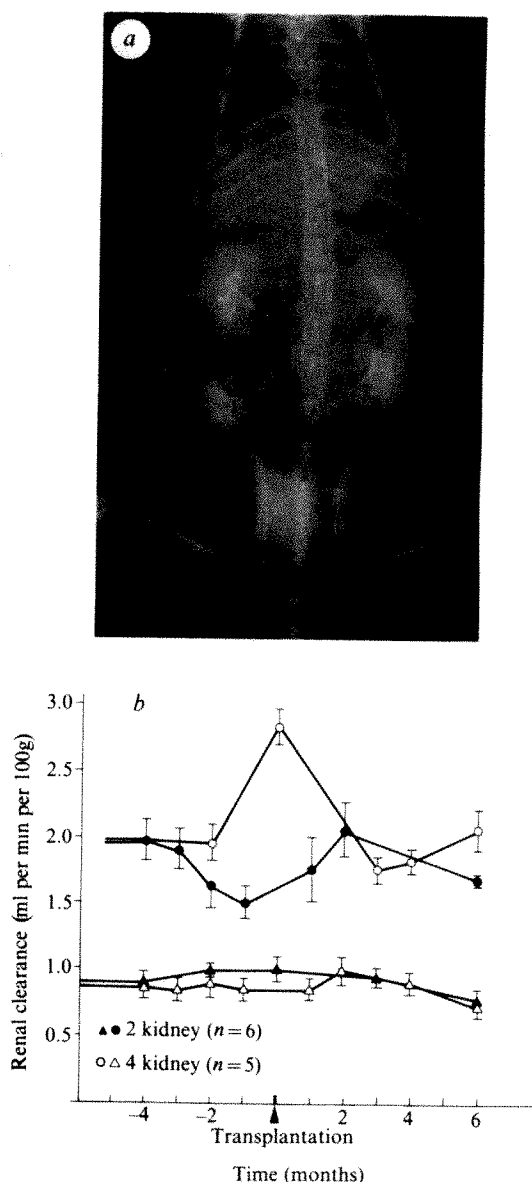

Fig. 1 *a*, Excretory urogram of a four-kidney rat 6 months after transplantation (25 min after injection of iodinated diatrizoate). The added (below) and original kidneys have maintained their size and excrete similar concentrations of contrast. *b*, Sequential renal clearances of ¹²⁵I-iothalamate (GFR, triangles) and ¹³¹I-Hippuran (RPF, circles) relative to body weight in five four-kidney rats (open symbols) and six intact sibling controls (closed symbols). Urograms were prepared with standard diagnostic X-ray equipment on rats anaesthetised with ether, 15–20 min after intravenous injection into the penile vein of 1.5 ml of Renographin 76 (67% diatrizoate, 37% bound iodine, Squibb).

The success of transplantation and the cross-sectional area of the kidneys were demonstrated on excretory urograms during the first week, at 4–6 months and at 1 yr (Fig. 1a). Cross-sectional areas and measurements made with calipers at transplantation and autopsy, showed that in four-kidney rats there was no obvious shrinkage of the original kidneys. We conclude that normal nephron size and aggregate renal mass do not adjust downwards as a consequence of a doubling of the number of nephrons.

Six four-kidney rats were used for long-term studies of glomerular filtration rate (GFR) and plasma renal flow (PRF). We added two kidneys because the doubling of functional mass should override the variability common to the results of clearance studies. A femoral or neck vein was cannulated with polyethylene tubing (PE-50) under ether anaesthesia and the rats were placed in individual metabolic cages (Nuclear Corp.). Saline was infused overnight (2 ml h^{-1} Harvard Instrument infusion pump). The next day, if the urinary output of the awake but restricted rats matched their input, saline was replaced by an isotonic solution of ^{125}I -sodium iothalamate (Glofil, Abbott) and ^{131}I -sodium iodohippurate (^{131}I -Hippuran, NEN) to measure GFR and RPF, respectively. Infusion was continued for another 5 h. Urine produced during the first hour was discarded and then all urine was collected for 4 h: its volume was measured and its radioactivity counted. To obtain blood counts we took blood at the beginning and the end of the collection period by warming the tails and making a cut in each of them. The two isotopes were measured simultaneously in a γ counter (Nuclear Chicago) with appropriate settings. The clearance of both isotopes was calculated as ml min^{-1} and adjusted for body weight. Although simultaneous counting of both isotopes introduced a systematic apparent lowering of the absolute values of RPF, it did not affect the comparison with the controls similarly processed.

GFR and RPF were measured three times in 4 months preoperatively and again at monthly intervals after surgery for 4 more months, and at 6 months for surviving rats. Total GFR and RPF increased with age and with increasing body weight during those 10 months in both groups, but not as a consequence of adding two kidneys. The stability of their GFR and RPF relative to body weight before and after transplantation is shown in Fig. 1b.

We next measured the relative contribution of each kidney towards overall clearance of the isotopes from the blood. We used dimercaptosuccinic acid (DMSA) a mercurial compound taken up selectively by the proximal convoluted tubules in the renal cortex. When bonded to the γ -emitter technetium-99 ($^{99\text{m}}\text{Tc}$ -DMSA), it is used clinically for scintiscanning of functioning renal cortex, usually to compare the uptake of two kidneys in one individual. We examined the uptake of $^{99\text{m}}\text{Tc}$ -DMSA in each kidney of six rats with three-kidneys, 7–9 months after transplantation, and of their intact sibling controls. We injected approximately $1 \mu\text{Ci}$ of $^{99\text{m}}\text{Tc}$ -DMSA (Medi Physics) intravenously: 16 h later anterior and posterior images (Fig. 2a) were recorded by a γ camera with a pinhole collimator (Sigma 400, Ohio Nuclear) and stored on a digital computer (Gamma-11, Digital Equipment). The count rate of the syringe containing the isotope was also stored on the computer before and after injection to determine the activity injected. Renal uptake was expressed for each kidney as a percentage of activity injected, corrected for background. Each value was an average of the uptake measured on the anterior and posterior projections.

Total uptake of DMSA varied from 21 to 30.5% of the injected dose, and in paired controls from 23.7–35%, thus being the same in rats with three kidneys as in a normal rat (Fig. 2b). Uptake by each of the two original kidneys varied from 7.6 to 12.3% of the injected dose, while for the controls the range was 10.3–18.2%. Paired measurements, made on the same day, always showed the uptake of each kidney in the control rat to be greater than that of either of the two original kidneys in the rat with three kidneys. The group difference on analysis by a

Fig. 2 a, Scintigram of three-kidney rat 16 h after injection of $^{99\text{m}}\text{Tc}$ -DMSA, in posterior view. The right kidney is uppermost and the transplanted third kidney lies transversely below the other two. b, Uptake of DMSA by the six three-kidney rats and sibling pair controls. The total uptakes of the three-kidney rats (right bars) are the same as those of controls (left bars). But the uptakes of the original two kidneys (the right kidney is black and the left is hatched in each bar) are consistently reduced ($P < 0.001$) in the three-kidney rats to accommodate the function of the added third kidney (clear sections of right-hand bars).

binomial probability table⁴ for a sample of 12 with no overlap is highly significant ($P < 0.0002$).

Taken together, our measurements demonstrate that the individual function of intact kidneys was reduced in response to the addition of functional renal tissue. Silber and Crudup tentatively concluded that a third kidney increased GFR by 50% (ref. 5), and an increase was suggested but not proved in our earlier work³. Our findings now conclusively show no increase in rats with three or four kidneys. Kidneys can increase their glomerular filtration and tubular reabsorption work acutely without an increase in size, as noted after uninephrectomy⁶. It now seems that on a day-to-day basis the kidney is capable of a wide range of autoregulation of function, including downward modulation, in response to the excretory needs of the whole body.

A feedback signal seems to enable the aggregate renal glomerular and tubular clearance of rats with two, three or four kidneys to remain a constant linear function of body weight. The signal is probably humoral because the transplanted kidneys responded as well as the intact kidneys. Another hint of a feedback signal comes from the work of Kover and Tost⁷, who connected the circulation of dogs to an isolated two-kidney organ preparation, acutely reducing the urine volume and urine sodium excretion of the original kidneys in proportion to that of the isolated kidneys.

The lack of detectable decrease in kidney size is consistent with the concept that a minimum renal size is achieved during normal growth and is 'obligatory'⁸, not influenced by low functional demand. Thus a baby (4 weeks) rat with a transplanted adult kidney grows up and has normal sized kidneys

(unpublished results of R. A. Dieppa, R.F.G., A.B. and J. McDonald). By contrast, compensatory hypertrophy is reversible to the 'obligatory' baseline size: transplanting a normal kidney into a rat living on a greatly hypertrophied half of one kidney (after removal of one and a half kidneys) reverses the hypertrophy of the half kidney⁹.

Dopaminergic nerve endings visualised by high-resolution autoradiography in adult rat neostriatum

Laurent Descarries, Olivier Bosler, France Berthelet & Michel H. Des Rosiers

Centre de Recherche en Sciences Neurologiques and Département de Physiologie, Faculté de Médecine, Université de Montréal, Montréal, Québec, Canada H3C 3T8

Nerve cells containing dopamine (DA), noradrenaline (NA) or serotonin possess powerful physiological mechanisms for the reuptake and storage of their own transmitter. Monoaminergic neurones may therefore be visualised by high-resolution autoradiography¹, provided that tritiated biogenic amines are retained in their sites of uptake and/or storage during suitable preparative histological procedures. Using this method, noradrenergic and serotonergic neuronal cell bodies and axon terminals have been specifically identified and examined in various parts of mammalian central nervous system². However, although the nerve cell bodies of central dopaminergic neurones have been similarly investigated after *in vivo* labelling with either ³H-DA or ³H-NA^{3–7}, the autoradiographic detection of dopaminergic nerve endings has remained problematic. Indeed, in previous studies after cerebroventricular infusion, superfusion or local instillation of ³H-DA or ³H-NA, light and electron microscope autoradiographs of neostriatum, the brain region richest in dopaminergic nerve endings, failed to exhibit the small clusters of silver grains typical of monoamine-labelled axonal varicosities^{8–10}. This suggested tracer displacement during histological processing, so we tested, after intraventricular administration of ³H-DA, a technique of tissue preparation developed in our laboratory for high-resolution autoradiographic visualisation of deoxyglucose-6-phosphate, a diffusible, water-soluble, unbound substrate¹¹. We report here that the rapid successive vascular perfusion of both a glutaraldehyde primary fixative and osmium tetroxide postfixative, which may be followed by dehydration and resin-embedding also carried out by perfusion, maintains a sufficient amount of ³H-DA *in situ* to ensure light and electron microscopic identification of DA axon terminals in rat brain¹².

All experiments were carried out in adult Sprague-Dawley rats (200–400 g), pretreated with a monoamine oxidase inhibitor (β -phenylisopropylhydrazine, 5 mg per kg intraperitoneally, 18 and 2 h earlier) and anaesthetised with sodium pentobarbital. 100–200 μ Ci of 3,4-dihydroxy [*ring*-G-³H]phenylethylamine

hydrochloride (³H-DA, specific activity 6.3 Ci mmol⁻¹, Amersham), diluted in 100–200 μ l of saline containing 1% ascorbic acid, were instilled stereotactically into a lateral cerebral ventricle for 1–2 h. In some cases, non-radioactive NA or serotonin (10⁻³ M) was added to this solution at a molarity 2–10 times higher than that of the tracer. Immediately thereafter, fixation was initiated by high flow-rate aortic-arch perfusion with 600 ml of 3.5% glutaraldehyde in 0.1 M cacodylate buffer (200 ml min⁻¹) and continued without interruption by perfusion with 500 ml of 0.5% osmium tetroxide in 0.2 M cacodylate buffer (same rate). Subsequent dehydration and embedding were also carried out by perfusion, using 3–4 l absolute ethanol and 3 \times 200 ml Epon-propylene oxide mixtures at increasing resin concentrations. The whole brain was then immersed for several hours in pure Epon and polymerised *in toto* at 60 °C¹¹. Samples of the caudate nucleus, ipsilateral to the instilled ventricle, were processed as semi-thin (1 μ m-thick) and thin (silver-gold) sections for light or electron microscope autoradiography, respectively, according to standard dipping techniques¹³. Other brain regions were examined by light microscope autoradiography only.

Three types of autoradiographic reactions were detected in neostriatum after intraventricular administration of ³H-DA. (1) Diffuse labelling, in the form of dispersed silver grains, overlaid all cytological constituents of the paraventricular region, with relative sparing of myelinated bundles. This ubiquitous reaction spread over 150–750 μ m and attenuated gradually with increasing distance from the ependyma. Its intensity was markedly diminished if non-radioactive NA had been added to the ³H-DA solution, indicating a common affinity of both catecholamines for nonspecific and/or artefactual binding sites. (2) Ependymal labelling (not illustrated) consisted of clumps of silver grains seemingly aligned along the ventricular edge in light microscope autoradiographs. In electron microscope autoradiographs, silver grains in this location mostly overlaid intracellular lysosome-like corpuscles predominating in the apical portion of ependymocytes, and plurivesicular or dense granular blebs protruding at the ventricular surface. Such labelling was not found after the addition of either non-radioactive NA or serotonin to the ³H-DA solution, suggesting competition between all three biogenic amines for binding at these ependymal sites. (3) Small and dense aggregates of silver grains, disseminated throughout the neuropil of paraventricular neostriatum, were the main finding of the present study (Fig. 1a). These were typical of labelled axonal varicosities having taken up and retained tritiated biogenic amine in high concentration¹⁴. They were most numerous immediately beneath the ependyma and also densely grouped in deeper patch-like areas extending between some myelinated fibre bundles. Electron microscope autoradiography confirmed that all such accumulations of tracer involved axonal enlargements containing synaptic vesicles. In fact, after a short period of exposure and low-sensitivity development, these were practically the only sites of silver grain localisation (Fig. 1b).

The above experiments give some indication of the signal-to-noise value of the axonal accumulations of ³H-DA. First, these were no longer visible when non-radioactive NA had been added to the ³H-DA solution, even though rat neostriatum receives little if any NA innervation¹⁵. This finding was consistent with the notion of competitive uptake of the two catecholamines in dopaminergic nerve endings^{16–18}. Second, the addition of non-radioactive serotonin to the ³H-DA solution had no apparent effect on either the number or the labelling intensity of the axonal accumulations, as would have been expected from a cross-reactivity of serotonergic nerve endings, abundant in neostriatum. Accordingly, there was no apparent labelling, even after the administration of ³H-DA alone, neither of the supraependymal serotonergic plexus nor of serotonergic axonal varicosities in supra-chiasmatic nucleus, two regions readily accessible to tracer. The latter observations were at variance with previous *in vitro* data indicating that serotonergic fibres have a capacity to take up exogenous DA¹⁹. The apparent discrepancy

Fig. 1 Light (*a*, *c*) and electron microscope (*b*) autoradiographs of paraventricular neostriatum, after intraventricular instillation of ^3H -DA *in vivo* followed by rapid double perfusion-fixation with glutaraldehyde and osmium tetroxide solutions. *a*, ^3H -DA was administered together with non-radioactive serotonin. Small and dense aggregates of silver grains, disseminated throughout the neuropil, signal the existence of axonal varicosities having taken up and retained the tracer. *b*, All accumulations of silver grains correspond to axonal enlargements containing synaptic vesicles. Some of these varicosities are seen in synaptic junction with dendritic profiles. *c*, ^3H -DA was administered 15 d after destruction of nigrostriatal dopaminergic neurones by 6-hydroxydopamine. The silver grain aggregates are no longer visible, which demonstrates their exclusive dopaminergic axonal origin. *a*, And *c*, D-19 development after 15 and 30 d of exposure, respectively. Scale bars, 50 μm . *b*, Paraphenylenediamine development after 30 d of exposure. Scale bar 0.5 μm .

between results of *in vivo* and *in vitro* experiments could be due to altered properties of severed serotonergic axon terminals incubated *in vitro*, and/or insufficient tissue concentration of ^3H -DA *in vivo* to induce interspecific labelling of serotonergic nerve endings.

Definite proof of the specific identity of the ^3H -DA-accumulating nerve endings in neostriatum was provided by autoradiographic data obtained after 6-hydroxydopamine lesioning²⁰ of the nigrostriatal dopaminergic system. In these rats, the neuronal cell bodies giving rise to the dopaminergic innervation of neostriatum, located in groups A-9 and A-10 of zona compacta and area ventralis tegmenti²¹, were selectively destroyed by local microinjection of the drug (8 μg in 4 μl of saline), 15 d before ^3H -DA administration. In agreement with previous reports, this pretreatment resulted in the conspicuous disappearance of all histofluorescent perikarya in substantia nigra, accompanied by a 90% decrease of endogenous DA content and total loss of histofluorescence in neostriatum²²⁻²⁴. Its consequence in light microscope autoradiographs of neostriatum was the virtual absence of any ^3H -DA

accumulations, confirming their dopaminergic axonal origin (Fig. 1*c*).

It seems likely that the greater diffusion of ^3H -DA than other biogenic amines during standard histological processing reflects some basic difference in the binding of these molecules inside their respective axon terminals²⁵. In fact, by comparison with noradrenergic nerve endings elsewhere in brain, the dopaminergic terminals of neostriatum are known to exhibit less distinct endogenous histofluorescence when visualised with the Falck-Hillarp technique²⁶; they also show a linear fluorescence-concentration relationship, as if some endogenous DA and/or its fluorophore were extracted from 'granules' or even from axoplasm during histochemical processing²⁷. Furthermore, greater amounts of endogenous or exogenous DA than NA are recovered in supernatant when synaptosomes or particulate fractions from regions containing these amines are being prepared by differential centrifugation^{25,28-30}. Such findings have already led to the suggestion that a significant proportion of the biogenic amine within dopaminergic nerve terminals is located extravesicularly, in a weakly bound and readily releasable

pool³¹. This same hypothesis could also explain why the cytochemical demonstration of small dense-core vesicles in neostriatal axon terminals has only been possible after loading with exogenous NA or false transmitter³²⁻³⁵, but has always failed with DA even after tissue incubation in high concentrations of this amine³².

The mechanisms by which histoprocessing by vascular perfusion permits the retention of loosely bound DA in neostriatal dopaminergic nerve endings remain to be elucidated. Preliminary experiments suggest that comparable results may be obtained after successive perfusion of both glutaraldehyde and osmium fixatives and subsequent dehydration and embedding carried out by immersion of tissue slices in the usual manner. It will be of interest to determine whether factors such as the velocity of the double fixation achieved by vascular perfusion, and/or the preservation of unbroken cell membranes throughout glutaraldehyde and osmium fixations, contributes in maintaining ³H-DA *in situ*.

In any event, the present study offered the first opportunity to examine dopaminergic nerve endings of neostriatum in conditions allowing not only their unequivocal identification, but also adequate preservation of their ultrastructural features. Until now, examination of some 100 sectional profiles of dopaminergic axonal varicosities in the paraventricular zone of neostriatum has shown that these are relatively small, averaging 0.5 µm in diameter (0.3–0.9 µm). Most contain round and clear small synaptic vesicles (30–50 nm), usually accompanied by one or more mitochondria; only a few exhibit large dense-core vesicles (80–120 nm). Note also that a fair number of ³H-DA-labelled varicosities may be seen in close apposition to small nerve cell bodies or in symmetrical synaptic junction with dendritic processes (Fig. 1b). Further elucidation of the fine structural features of neostriatal dopaminergic axonal varicosities should help to resolve present controversies regarding the junctional versus non-junctional relationships of these nerve terminals³⁵.

In regions of the brain known to receive a mixed dopaminergic and noradrenergic innervation (for example hypothalamic paraventricular nucleus and median eminence), the distribution of axon terminals detected in light microscope autoradiographs suggests that both types of catecholaminergic nerve endings are simultaneously labelled with ³H-DA after double perfusion of glutaraldehyde and osmium fixatives. Selective cytolytic removal of noradrenergic afferents and/or pharmacological inhibition of their uptake systems, might therefore prove necessary for achieving a specific autoradiographic identification of dopaminergic nerve endings within such parts of the nervous system.

We thank C. de Montigny and T. A. Reader for their histo- and biochemical analyses, K. C. Watkins, S. Garcia and D. Cyr for technical assistance, and J. Manson for reviewing the manuscript. These studies were supported by MRC grant MT-3544 (to L.D.), funds from CAFIR and the Magali Ducharme and Joseph Rhéaume foundations at the Université de Montréal, and a CRSQ fellowship (to O.B.).

Role of NK cells in tumour growth and metastasis in beige mice

James E. Talmadge*†, Kenneth M. Meyers‡, David J. Prieur* & Jean R. Starkey*

* Department of Veterinary Microbiology and Pathology, Washington State University

‡ Department of Veterinary and Comparative Anatomy, Pharmacology and Physiology, Washington State University, Pullman, Washington 99164

Although natural killer (NK) cells are thought to give the host a spontaneous resistance against tumours and have been postulated to act *in vivo* as surveillance cells¹, definitive data in support of these hypotheses has not been obtained. Recently the beige (bg) mouse, a morphological homologue of the human Chediak-Higashi (CH) syndrome²⁻⁴, was shown to be deficient in NK activity⁵. Specifically, spleen cells of bg mice were demonstrated to be incapable of *in vitro* natural cytotoxicity against tumour cells⁵. We report here that a tumour line, modified to be sensitive to NK cytotoxicity by *in vitro* culture, demonstrated *in vivo* an increased growth rate, faster induction time and an increased metastatic capability in bg compared to control mice. This was not found with a tumour line insensitive to NK activity (without *in vitro* culture). *In vivo* activation of NK cells in bg and control mice resulted in a decrease in tumour growth rate and metastatic frequency. These results demonstrate that NK cells have an important function in the host's control of tumour growth and metastasis.

NK cells seem to be pre-T cells that do not require thymic maturation. This could account for their presence in athymic nude mice⁶. The level of NK cell activity is genetically controlled⁷, age-dependent⁸ and may be augmented by numerous agents, including infection with lymphocytic choriomeningitis virus (LCMV)⁹. Induced NK-cell activity peaks 3 d after injection of LCMV and decreases to normal levels by day 8 (ref. 10). Interferon levels directly parallel the rise and decrease of NK activity¹¹ suggesting that the increased NK-cell activity in LCMV infected mice is mediated by the viral induction of interferon¹⁰. The sensitivity of tumour cell lines to NK-cell activity varies directly with the length of time they have been cultured *in vitro*, and *in vivo* passaged cell lines are often insensitive to NK cytotoxicity⁸. At least 3 weeks of *in vitro* culture are required for a tumour line to develop an increased sensitivity to NK cytotoxicity¹².

Growth parameters and metastatic abilities of the malignant melanoma tumour B16 were studied in syngeneic normal (+/bg) and bg (bg/bg) C57BL/6 mice. B16 tumours which were passaged *in vivo* and cultured *in vitro* only a short time were insensitive to NK lysis (Table 1A). However, increased *in vitro* culture time resulted in the acquisition of a sensitivity to NK lysis

† To whom correspondence should be addressed at: Frederick Cancer Research Center, Biology of Metastasis Section, PO Box B, Frederick, Maryland 21701.

by the tumour cells (Table 1A). Table 1 also demonstrates that spleen cells from normal mice exhibit NK activity but that spleen cells from *bg* mice do not exhibit unstimulated NK activity, confirming a previous report⁵. LCMV induction of NK activity markedly enhanced cytotoxicity against B16 cells cultured *in vitro* for 32 d as well as against B16 cells cultured *in vitro* for only one day that were refractory to unstimulated NK activity (Table 1A).

The injection of LCMV into 6–8-week-old mice increased NK activity in both normal and *bg* mice. In normal mice NK activity peaked on day 3 and returned to normal by day 6 following LCMV injection. The *bg* mice expressed NK activity 24 h after LCMV injection. This activity peaked on day 5, and decreased more slowly than in normal mice, a finding in agreement with that of Kiessling¹².

Tumours insensitive to NK lysis required the same time to achieve 100% tumour induction and grew to essentially the same mean tumour volumes in normal and *bg* mice (Table 2). However, tumour cells sensitive to NK lysis had longer tumour induction times, slower growth rates (data not shown) and produced smaller tumours in normal compared to *bg* mice (Table 2). The parameters of tumour growth for both the NK-insensitive and -sensitive tumour lines were reduced when injected into LCMV-infected normal or *bg* mice (Table 2). Spontaneous metastasis was assessed following subcutaneous tumour growth in a pinna, followed by resection of the ear on day 21, and necropsy of mice at the onset of morbidity¹³. Approximately the same number of metastases were found in normal and *bg* mice injected with NK-insensitive tumour cells

A, Cultured target cells were labelled with ⁵¹Cr (2×10^7 cells were incubated with 200 μ Ci ⁵¹Cr for 40 min at 37 °C), washed, allowed to attach to the wells of a microtest II dish (5,000 cells per well) for 4 h, and washed again. Complete medium (200 μ l) containing effector cells from the spleens of: (1) *bg*; (2) normal; or (3) normal mice infected 3 d previously with $1-2 \times 10^4$ plaque-forming units (PFU) of LCMV were then added. Following 6 h incubation at 37 °C 100- μ l aliquots of the supernatant were removed and counted in a γ counter. Spontaneous release was obtained from wells incubated without effector cells and was always less than 10% of total release obtained with 2% SDS (450 cpm/6,000 cpm total release). NK activity is expressed as the per cent cytotoxicity = (test c.p.m. – spontaneous c.p.m.)/(total c.p.m. – spontaneous c.p.m.).

B, NK lysis activity was assayed as in experiment A, using B16 target cells which had been cultured *in vitro* for 32 d. Mice that were 6–8 weeks of age were injected with $1-2 \times 10^4$ PFU of LCMV on consecutive days and assayed on the same day using an effector: target ratio of 100:1.

Table 2 Role of NK cells in modifying subcutaneous growth and metastasis of B16 tumour cells

Time required to reach 100% tumour induction, or the percentage of animals with tumours 21 days following tumour injection

Mouse genotype	LCMV	B16 cells cultured for:	
		5 days	32 days
<i>bg/bg</i>	–	13 days	14 days
+/ <i>bg</i>	–	14 days	45%
<i>bg/bg</i>	+	16 days	17 days
+/ <i>bg</i>	+	80%	80%

Mean tumour size \pm s.e.m. 21 days following tumour cell injection (mm³)

Mouse genotype	LCMV	B16 cells cultured for:	
		5 days	32 days
<i>bg/bg</i>	–	105 \pm 26	93 \pm 22
+/ <i>bg</i>	–	175 \pm 57	4.1 \pm 1.2
<i>bg/bg</i>	+	81 \pm 36	42 \pm 19
+/ <i>bg</i>	+	25 \pm 15	5.4 \pm 1.4

Incidence of pulmonary metastases (mean number of metastases \pm s.e.m. per mouse)

Mouse genotype	LCMV	B16 cells cultured for:	
		5 days	32 days
<i>bg/bg</i>	–	5.4 \pm 0.95	7.1 \pm 0.88
+/ <i>bg</i>	–	6.1 \pm 0.63	0 \pm 0
<i>bg/bg</i>	+	0 \pm 0*	0 \pm 0*
+/ <i>bg</i>	+	0 \pm 0*	0 \pm 0

The mice received 10^5 cells in a 0.05-ml aliquot subcutaneously in one ear. Mice with LCMV had received $1-2 \times 10^4$ PFU 2 days previously. The tumour size was measured in three dimensions after 21 days of growth and the volume calculated¹⁷. The tumour bearing ear was amputated at this time. 15 days later the mice were necropsied and the number of spontaneous metastases counted. $n = 10$ mice.

* Several of these mice had extensive peripheral lymph node tumour growth.

Table 3 Role of host NK activity and tumour sensitivity to NK lysis in modifying the incidence of metastases following intravenous injection of B16 tumour cells

A	Mouse genotype	LCMV	Mean no. lung metastases \pm s.e.m. per mouse	
			B16 tumour cells cultured for:	
			5 days	32 days
	<i>bg/bg</i>	–	6.7 \pm 0.88	8.4 \pm 2.71
	+/ <i>bg</i>	–	9.2 \pm 1.48	0 \pm 0
	<i>bg/bg</i>	+	3.1 \pm 0.5	4.2 \pm 0.73*
	+/ <i>bg</i>	+	3.3 \pm 0.31	0 \pm 0
B			2 days	40 days
	<i>bg/bg</i>	–	17.4 \pm 2.27	16.8 \pm 2.78
	+/ <i>bg</i>	–	11.0 \pm 1.45	0 \pm 0

Mice received 0.10 ml of a single cell suspension of B16 cells (experiment A, 20,000 cells; experiment B, 50,000 cells). These cells had been cultured for 5 or 32 days (experiment A), and 2 or 40 days (experiment B). The mice injected with LCMV received $1-2 \times 10^4$ PFU of LCMV 2 days before tumour cell injection. After 15 days the mice were necropsied and the number of pulmonary metastases counted using a dissecting microscope. $n = 10$ mice.

* These mice had five extra pulmonary metastases, three ovarian and two renal.

(Table 2). However, the incidence of spontaneous metastasis was markedly reduced with NK lysis sensitive tumour cells injected into normal mice compared to *bg* mice. The metastatic incidence was greatly reduced in mice with LCMV-activated NK cells bearing NK-insensitive tumours in normal or *bg* mice and NK-sensitive tumours in *bg* mice.

The metastatic abilities of NK-sensitive and -insensitive B16 cells were also studied using the lung colony assay (Table 3). No difference was found in the experimental metastatic ability of NK-insensitive tumour cells in normal or *bg* mice (Table 3). However, NK-sensitive tumour cells were metastatic using the lung colony assay in *bg* mice but not in normal mice (Table 3). Metastatic ability seemed to correlate with the tumour cells' sensitivity to NK lysis and with the level of NK activity. This conclusion was further substantiated using mice of both genotypes infected with LCMV. These mice had fewer lung colony foci following injection with either NK lysis sensitive or insensitive tumour cells compared to mice without activated NK cells, except for NK-sensitive cells injected into normal mice where they were already non-metastatic.

A role for NK cells in metastasis was initially suggested by the observation that transplanted tumours rarely metastasise in nude mice¹⁴ which have high levels of NK activity¹⁵. Also there is a direct correlation between the level of NK activity in different mouse strains and the short-term survival of tumour cells labelled with ¹²⁵I-iodoxuridine using a lung colony assay¹⁶. An NK-sensitive tumour injected into *bg* mice (deficient in normal NK activity) is induced faster, grows more rapidly and has more metastases than the same tumour in normally NK-constituted mice. These differences were not present with a tumour insensitive to NK cells. Normal and *bg* mice with

LCMV-activated NK cells, however, exhibited a reduced growth rate and reduced metastatic incidence of both NK lysis sensitive and insensitive tumour cells. These results suggest an important role for NK cells in the host's control of malignant disease.

We thank Dr R. Welsh and Dr R. Kiessling for helpful discussions and Dr Welsh also for providing LCMV. This study was supported by NIH grant RR 00515 and by American Cancer Society Institutional support grant no. IN-119. D.J.P. is the recipient of an NIH Research Career Development Award (RR00003).

Low natural *in vivo* resistance to syngeneic leukaemias in natural killer-deficient mice

Klas Kärre, Gunnar O. Klein, Rolf Kiessling, George Klein & John C. Roder*

Department of Tumor Biology, Karolinska Institutet, S-104 01 Stockholm 60, Sweden

Natural killer (NK) cells, which occur at high levels in normal non-immune individuals of several species, have the capacity to lyse certain tumour cells *in vitro*, and have been proposed as a first level of defence against tumour growth *in vivo*¹⁻³. Evidence for this comes mainly from the murine system, where certain F₁ hybrid or T-cell deficient mice with high NK activity resist growth of transplanted tumours better than do normal syngeneic controls with lower NK activity⁴⁻⁶. Recent studies of the beige mutation on the C57BL mouse strain background, previously proposed as an animal homologue of the human Chediak-Higashi syndrome^{7,8}, have revealed a new model for analysing anti-tumour effector mechanisms in the intact syngeneic host^{9,10}. The recessive beige gene (*bg*⁺), which affects melanosome and granulocyte lysosome functions^{11,12}, also causes a profound (but not total) depression of NK activity whereas other anti-tumour effector mechanism mediated by T cells and macrophages remain relatively intact¹³. It was important, therefore, to test the tumour susceptibility of beige mice as a first direct test of the hypothesis that NK cells are involved in surveillance against neoplasia. In partial confirmation of this hypothesis, we report here that failure of small threshold doses of one virally and one chemically induced transplantable leukaemia to grow out in syngeneic mice partly depends on a rapidly acting host defence mechanism. This mechanism is deficient in *bg/bg* mice, which develop palpable, progressively growing tumours faster and at a higher frequency than do phenotypically normal *+/bg* littermates.

The benzpyrene-induced EL-4 and the Rad-LV-induced P-52-127-166 leukaemias of C57BL/6 origin, are both highly resisted by certain C57BL F₁ hybrids that have high NK activity *in vitro*^{14,15}. Also, low-dose inocula of the *in vivo* maintained ascites lines of the two leukaemias behaved similarly; subcutaneous (s.c.) inoculation in a transplantation test yielded higher tumour take incidence in *bg/bg* mice than in heterozygous littermates (Fig. 1). The differences were most striking in

the early phase of the observation period, with a majority of the total tumour takes in *bg/bg* registered within 2 weeks (68% with EL-4, 69% with P-52-127-166) whereas only a small part of the tumours in *+/bg* mice were palpable at this time (31% with EL-4, 14% with P-52-127-166). Thus, in addition to the increased incidence of takes in mutant mice, the progressively growing tumours appeared with a shorter latency than in controls. This was also reflected in the larger mean tumour diameter by 2 and 3 weeks and the earlier deaths among tumour-bearing *bg/bg* than *+/bg* mice (Fig. 1 legend).

The outcome of a long-term transplantation test can be influenced by a variety of host factors. However, most of the tumours in *bg/bg* mice had appeared after the short period of 2 weeks, after which the tumour incidence curves of *bg/bg* and *+/bg* became virtually parallel. This indicated that the defect in natural resistance of beige mice involved early events after tumour inoculation. Further support for this was obtained in a test system where the short-term survival of intravenously (i.v.) injected ¹²⁵I-iododeoxyridine (IUdR) labelled leukaemia cells is monitored, previously proposed as a most appropriate *in vivo* assay for natural rejection mechanisms^{16,17}, including NK cells^{18,19}. The heterozygous control mice eliminated P-52-127-166 ascites cells more efficiently than did beige mice, measured either as total, pulmonary or splenic radioactivity retained 18 h after i.v. injection (Fig. 2), although in the spleen, differences were already detectable after 4 h (Fig. 2 legend). The results suggest that *bg/bg* mice may lack an important mechanism for rapidly eliminating tumour cells, for example, as blood-borne metastases in the lungs and spleen.

Our findings in *in vivo* tests correlate well with the *in vitro* measured splenic NK activity against both tumours tested. EL-4 or P-52-127-166 cells had a low, but significant, sensitivity to *+/bg* spleen cell cytotoxicity (5-10% specific lysis) whereas *bg/bg* spleen consistently gave values below 3% specific lysis (Fig. 3).

Augmentation of the low NK levels against EL-4 and P-52-127-166 occurred in mice receiving the low tumour cell dose used in the transplantation tests (Fig. 3). The NK activities of *+/bg* as well as *bg/bg* mice were increased, although relative differences between the groups were maintained. In both tumour-inoculated and control groups, *bg/bg* mice gave values corresponding to a ninefold dilution of *+/bg* splenocytes in terms of lytic units. As has been shown with larger doses of tumour cells²⁰, the augmented cytotoxicity observed here was mediated by non-adherent cells (Fig. 3) which were relatively resistant to treatment with anti-Thy 1.2 plus complement, and declined in activity after day 3 to values comparable to those in non-inoculated control mice (unpublished observation). Such augmented NK activity, induced during the transplantation

tests, may account for *in vivo* resistance against tumour cells which show very low susceptibility to *in vitro* lysis by NK cells from normal mice.

Several different phenotypic manifestations of the beige mutation may be partly responsible for the low natural resistance against transplanted tumours in *bg/bg* mice observed here. However, our results from the two *in vivo* test systems suggest that early events are of major importance for the final outcome of tumour growth; this would argue against adaptive mechanisms requiring proliferative expansion of specific clones, as in a cytotoxic T-cell response. Furthermore, the early more efficient *in vivo* elimination of leukaemia cells in *+/bg* mice was paralleled by a greater cell-mediated cytotoxicity *in vitro* against the same tumours which was independent of adherent cells. This makes the involvement of monocytes or macrophages, proposed as responsible for natural surveillance in other systems^{21,22}, less likely. Finally, *bg/bg* mice generate highly efficient T-killer cells *in vivo* after injection of P815 tumour cells, and anti-tumour effects mediated by macrophages are also normal¹³. Although we cannot exclude the possibility that mechanisms which are

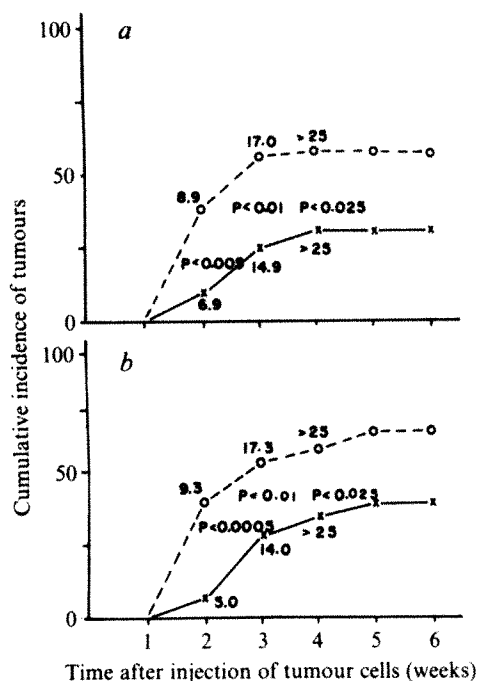

Fig. 1 Cumulative tumour take incidences in *+bg* and *bg/bg* mice. EL-4 or P-52-127-166 cells were collected from the ascitic fluid of C57BL/6 mice (in which the tumours were propagated *in vivo* in our animal colony) and washed once in balanced salt solution (BSS). EL-4 (5×10^3) or P-52-127-166 (10^3) cells were then injected s.c. in the back of *+bg* or *bg/bg* littermates, obtained by crossing C57BL/6 *+bg* and C57BL/6 *bg/bg* breeders (originally purchased from Jax Laboratories and maintained by continuous brother-sister mating according to a backcross-intercross scheme in our animal colony). The challenging cell doses were chosen from pretitration experiments so that tumours would grow progressively only in a fraction (30–40%) of syngeneic *+bg* mice. By this procedure, the inoculum would be large enough to be able to establish a growing tumour mass, but still so small that it would allow detection of any impairment of natural resistance in *bg/bg* mice by an increased incidence of tumours. Curves and *P* values (χ^2 -test) compare the tumour take incidence in *+bg* (x) and *bg/bg* (o) at weekly intervals, with figures at each time point referring to mean tumour diameter (out of three perpendicular measurements) in mm. a), EL-4 (four experiments with a total of 52 *+bg* and 38 *bg/bg* mice tested): out of all *+bg* mice that developed progressively growing tumours, 6% had died by week 3 and 65% by week 4; the corresponding figures for *bg/bg* mice were 22% by week 3 and 95% by week 4. b), P-52-127-166 (6 experiments with a total of 70 *+bg* and 56 *bg/bg* mice tested): out of all *+bg* mice that developed progressively growing tumours, 0 had died by week 3, 21% by week 4 and 69% by week 5; the corresponding figures for *bg/bg* mice were 6%, 57% and 89%, respectively. No new palpable tumours appeared after 5 weeks (mice were kept for 8–12 weeks after tumour injection). Preliminary experiments with 10-fold higher tumour cell doses have yielded 80–90% takes in beige as well as control animals, although latency and survival data show faster tumour growth in *bg/bg* mice.

Fig. 2 *In vivo* elimination of $^{125}\text{IUdR}$ -labelled leukaemia cells in *+bg* and *bg/bg* mice. P-52-127-166 ascites cells were labelled by intraperitoneal injection of $50 \mu\text{Ci } ^{125}\text{I}$ -labelled 5-iodo-2'-deoxyuridine ($>5 \text{ Ci per mg}$, Radiochemical Centre) 3 days after passage of 10^7 cells. After 6 h, cells were collected by peritoneal washes, counted, washed four times in BSS and injected in a lateral tail vein of *+bg* and *bg/bg* mice (1×10^6 cells per mouse). Groups of four or five animals were killed after 4 and 18 h, and the spleens and lungs were removed. Whole body and organ counting were carried out in an Intertechnique γ spectrometer. Symbols represent total (whole body + spleen + lungs), splenic and pulmonary retained radioactivity (calculated as percentage of total injected) in individual *+bg* (x) and *bg/bg* (o) mice after 18 h. Vertical columns represent arithmetic means, and *P* values refer to statistical analysis by a Student's *t*-test. Four hours after injection, the corresponding values were as follows (mean and range): *bg/bg*, 83 (71–89); *+bg*, 82 (77–80); lungs: *bg/bg*, 61 (57–69); *+bg*, 54 (49–60); *P* < 0.1; spleen: *bg/bg*, 0.52 (0.47–0.56); *+bg*, 0.41 (0.33–0.52), *P* < 0.05.

Fig. 3 Splenic NK activity of normal or tumour-inoculated *+bg* and *bg/bg* mice. Three days after s.c. inoculation of BSS or 10^3 P-52-127-166 cells, mice were killed and spleen cell suspensions prepared in complete RPMI with 10% fetal calf serum. Cells from three pooled spleens were incubated in a nylon wool column²⁶ and thereafter used as effectors in a standard 8-h ^{51}Cr release assay (as previously described) against EL-4 (a) or P-52-127-166 (b) cells. Values represent the mean of triplicate samples (triplicate variation < 5% of mean value). Spontaneous release was 11.2% for EL-4 and 15.1% for P-52-127-166. Unfractionated control cells were in all cases slightly less efficient than nylon wool-passed cells as cytotoxic effectors (not shown). ●, *+bg* (BSS); ○, *+bg* (10^3 P52-127-166); ▲, *bg/bg* (BSS); △, *bg/bg* (10^3 P52-127-166).

unaffected by the beige mutation contribute to natural resistance, our results indicate that NK cells have a major role in the cell-mediated *in vivo* defence against transplanted leukaemias observed in syngeneic phenotypically normal (*+bg*) mice. This has important implications for the evaluation of the influence of NK cells on primary tumour formation and growth in the normal autochthonous host. If the high NK-cell activity of nude mice is the explanation for their low or 'normal' incidence of tumours and their ability to resist growth of certain murine as well as human transplanted tumours, it is clear that a double mutant combining the beige and the nude defects would be a useful tool

for future research. Such a defect is not lethal, and we have recently been able to produce double mutant mice by a series of crosses and intercrosses between C57BL/6 *bg/bg* and C57BL/6+/*nu* mice. These C57BL/6 *bg/bg*, *nu/nu* mice are now being characterised immunologically.

In conclusion, the experimental model provided by the beige mutation provides strong additional support for the notion that NK cells may be involved in anti-tumour surveillance *in vivo*. Conclusive evidence should come from further studies of primary induced or spontaneous tumours in beige mice. In this context, it is interesting that humans bearing the Chediak-Higashi gene have an even greater impairment (500-fold) in NK

function²³ and a corresponding increase in the incidence of a spontaneous lymphoproliferative disorder which is thought to be malignant²⁴.

During these studies, we became aware of a similar study in progress by Talmadge *et al.*²⁵ (*Nature*, this issue), showing faster growth and increased metastasis of *in vitro* cultured syngeneic melanoma cells in *bg/bg* mice.

We thank Dr Mona Hansson for helpful discussions, and Ms Maj-Lis Solberg and Ms Margareta Hagelin for technical assistance. This investigation was supported in part by grants 1R01 CA 26782-01 and 1R01 CA 14054-07 from the NCI, DHEW, and by grants from the Swedish Cancer Society.

Retinoids specifically enhance the number of epidermal growth factor receptors

Anton M. Jetten

Differentiation Control Section, Laboratory of Experimental Pathology, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20205

Retinoids elicit many biological and biochemical responses from cells *in vitro*¹⁻⁵. One widely used criterion for the responsiveness of cells to retinoids is inhibition of growth; retinoids reduce the saturation density and/or growth rate of many normal and tumorigenic cell lines^{2,6,7}. Propagation of eukaryotic cells has been demonstrated to be dependent on the presence of macromolecular growth factors such as epidermal growth factor (EGF)⁸⁻¹⁰, which can stimulate proliferation of epithelial and fibroblastic cell lines. We now describe the effect of retinoids on the binding of EGF to its receptor. Retinoic acid enhances binding of ¹²⁵I-labelled EGF to various fibroblastic and epidermal cell lines. It has no marked effect on the affinity of this growth factor for its receptor, but increases the number of EGF receptor sites. Retinoic acid has little effect on the binding of concanavalin A (Con A) and insulin, indicating the specific nature of the action of retinoids on cell-surface glycoproteins. Treatment of cells with the phorbol ester 12-*O*-tetradecanoyl phorbol-13-acetate (TPA) and retinoic acid shows poor antagonism between these compounds on EGF binding. It has been previously shown that retinoids induce or stimulate differentiation of embryonal carcinoma cells¹¹⁻¹³. EGF binding can be used as a marker to monitor differentiation of these cells.

When sparse cultures of 3T6 cells are treated with retinoic acid the growth rate and saturation density are reduced, cells become more adhesive and have less tendency to overlap⁶. Figure 1 shows the effect of various concentrations of retinoic acid and its phenyl analogue on the binding of ¹²⁵I-labelled mouse EGF to 3T6 cells. Retinoic acid markedly increases binding of ¹²⁵I-EGF to its receptor, whereas the phenyl analogue does not affect this binding. Maximum binding, five- to sevenfold above control levels, occurs at a concentration of

3×10^{-6} M retinoic acid. The effect of retinoic acid on EGF binding is reversible; 3 days after the removal of retinoic acid, levels of EGF binding are reduced to those of control cells (not shown).

Because for certain cell lines, EGF binding is strongly dependent on cell density^{15,16}, the retinoic acid-induced enhancement of EGF binding might be related to the reduction of saturation density caused by this compound. However, we found no dependency of EGF binding on cell density in either retinoic acid-treated 3T6 cells ($1-6 \times 10^4$ cells cm^{-2}) or control cells ($1-12 \times 10^4$ cells cm^{-2}).

To determine the structural specificity of retinoids for stimulating EGF binding, we studied the effect of several analogues on the binding of this growth factor to 3T6 cells (Table 1). Retinoic acid and its *cis* analogue are the most potent derivatives tested, whereas the phenyl, pyrimidyl, methyl ether and ethylamide analogues are inactive. Retinol and retinyl acetate also increase EGF binding, although less effectively than retinoic acid. The specificity of the various analogues for stimulating EGF binding parallels that with which they increase adhesiveness and reduce saturation density of 3T6 cells² and induce differentiation of embryonal carcinoma cells¹³. Furthermore, except for retinol and retinyl acetate, which do not bind to the retinoic acid-binding protein, the effect of all analogues on EGF binding correlates exactly with their capacity to compete with retinoic acid for the binding site of this binding protein^{2,13,17}. We have found that retinyl acetate is rapidly converted to retinol and that 3T6 cells do not contain detectable amounts of retinol-binding protein (unpublished results). The activity of both retinol and retinyl acetate, therefore, cannot be due to the involvement of this binding protein but may be explained by the conversion of retinol to a metabolite that is able to bind effectively to the retinoic acid-binding protein.

To investigate whether the enhancement of EGF binding induced by retinoids is due to either an increase in unoccupied receptors or increased affinity, the effect of EGF concentration was determined. As shown in Fig. 2, retinoic acid has little effect on the affinity of ¹²⁵I-labelled mouse EGF for its receptors. Scatchard plot analyses indicate dissociation constants of 4.1×10^{-10} M and 4.5×10^{-10} M for retinoic acid-treated and control cells, respectively. However, the number of unoccupied EGF receptor sites is markedly increased from 2.87×10^4 receptors per cell for control cells to 1.51×10^5 receptors per cell after retinoic acid treatment.

Fig. 1 Effects of retinoic acid at various concentrations on the binding of ^{125}I -labelled mouse EGF to 3T6 cells. Cells were grown in DMEM containing 10% calf serum for 3 days in the presence of either retinoic acid dissolved in ethanol or ethanol alone (0.15% v/v final concentration). After trypsinisation cells were subcultured in 35-mm cluster dishes ($1-2 \times 10^5$ cells per well). After 48 h incubation, binding of EGF was determined in duplicate as described by Todaro *et al.*^{16,18}. The medium was aspirated and the cells washed twice with 2 ml binding buffer (DMEM containing 1 mg ml^{-1} bovine serum albumin and 50 mM N,N -bis-(2-hydroxyethyl)-2-aminoethanesulphonic acid adjusted to pH 6.8). In the binding assays 1 ml binding buffer containing 0.825 ng of ^{125}I -labelled mouse EGF (Collaborative Research, 1.4×10^5 d.p.m.) was added to each well. After 60 min at 37°C unbound ^{125}I -EGF was removed, cells were washed four times with 2 ml binding buffer and solubilised in 0.75 ml lysing buffer (0.1 M Tris-HCl, pH 7.4, containing 0.5% SDS and 1 mM EDTA) and the wells washed twice with 0.5 ml lysing buffer. Radioactivity was counted in a Packard γ -counter. Nonspecific binding was determined in the presence of $10 \mu\text{g}$ unlabelled mouse EGF (Collaborative Research) and consisted of 100–300 d.p.m. per 10^6 cells. Cell number was determined in a Coulter counter; in all cases binding was determined at equal cell density ($\sim 5 \times 10^5$ cells per well). ●, Retinoic acid; ○, phenyl analogue of retinoic acid.

To test the generality of its effect on EGF binding, we studied the action of retinoic acid on several other cell lines and two other ligands, Con A and insulin (Table 2). Retinoic acid increases the binding of EGF in several other mouse fibroblast cell lines, including two clones of 3T12, two of 3T3 and one 3T3 derivative obtained by transformation with the chemical carcinogen dimethylbenzanthracene. Another 3T3 derivative transformed by benzo(a)pyrene shows very low levels of EGF binding which are not increased by treatment with retinoic acid. Also, melanoma S91M3 cells show very low binding of EGF, whereas treatment with retinoic acid enhances this binding. Retinoic acid stimulates severalfold the binding of EGF to two mouse epidermal cell lines, JB-6 and its tumorigenic derivative T62 obtained after selection by treatment with TPA¹⁸ but has little effect on EGF binding to human epidermoid carcinoma cells A431 and to Syrian hamster kidney cells BHK-21. Treatment of 3T3 cells with retinoic acid inhibits cell growth, enhances cell-to-cell substratum adhesiveness, increases production of glycosaminoglycans and stimulates EGF binding, whereas none of these characteristics is affected in its virus-transformed derivative 3T3SV. This difference can be attributed, respectively, to the presence and absence of retinoic acid-binding protein in these two cell lines².

Retinoic acid treatment has little effect on Con A and insulin binding (Table 2). It increases Con A binding to 3T6 and 3T12 C1A cells by 41% and 29%, respectively, but this binding is virtually unchanged in 3T3 and 3T3SV cells. Retinoic acid does not affect binding of insulin to any of these cell lines. These results indicate a specific nature of the action of retinoids on cell-surface glycoproteins.

Table 1 The effect of retinoids on the binding of ^{125}I -labelled mouse EGF to 3T6 cells

Basic chemical structure	R	^{125}I -EGF binding (pg per 10^6 cells)	Relative binding
	CH_2OH^*	230.4	2.71
	$\text{CH}_2\text{OCOCH}_3$	257.6	3.03
	COOH^\dagger	483.2	5.68
	CH_2OCH_3	97.0	1.14
	COOH	324.3	3.81
	CONHC_2H_5	91.2	1.07
	COOH	478.2	5.63
	COOH	83.2	0.98
	COOH	356.0	4.18
	COOH	71.6	0.84

Cells were grown for 5 days in the presence of 10^{-5} M of the indicated retinoid. The binding of ^{125}I -EGF was determined as described in Fig. 1 legend; 1.25 ng ^{125}I -EGF per ml (counts 1.2×10^5 d.p.m.) was added. Control cells bound 85.0 pg per 10^6 cells. The relative binding is defined as binding of ^{125}I -EGF to retinoid-treated cells/binding to control cells.

* , Retinol; † , retinoic acid.

Several reports have shown antagonism between retinoic acid and the tumour promoters phorbol esters. Retinoic acid inhibits induction of ornithine decarboxylase by phorbol esters¹⁹ and prevents growth in soft agar induced by sarcoma growth factor and phorbol esters^{20,21}. Phorbol esters reduce EGF binding by decreasing its affinity for its receptor¹⁴. When TPA is added to 3T6 or 3T12 C1A cells, EGF binding is reduced within 5 h, whereas EGF binding to retinoic acid-treated cells increases gradually with time, becoming optimal after 3 days of treatment (Table 3). Cells incubated simultaneously for 5 h with TPA and retinoic acid show no antagonism between these compounds on

Fig. 2 Effect of EGF concentration on binding of ^{125}I -labelled mouse EGF to retinoic acid-treated and control 3T6 cells. Cells were treated with 10^{-5} M retinoic acid for 5 days. The binding assays were carried out as described in Fig. 1 legend. Data in the main figure were used for Scatchard plot analyses (inset). ○, Control; ●, retinoic acid treated cells; B/F, bound/free EGF.

Table 2 Effect of retinoic acid on the binding of EGF, Con A and insulin to various cell lines

Cell type	Designation	Binding of ^{125}I -ligand (10^3 d.p.m. per 10^6 cells)					
		Control	EGF RA-treated	Control	Con A RA-treated	Control	Insulin RA-treated
Mouse fibroblast	3T6	3.82	25.98 (6.8)	48.40	68.24 (1.41)	1.06	0.89 (0.84)
Mouse fibroblast	3T12CLA	2.18	16.54 (7.6)	32.36	41.83 (1.29)	0.61	0.60 (0.98)

Mouse epidermal	JB-6†	3.70	9.36 (2.53)				
	T62†	1.74	5.90 (3.4)				
Mouse melanoma	Cloudman S-91 M3	0.03	0.20 (6.7)				
Syrian hamster kidney	BHK-21	3.81	3.04 (0.8)				
Human epidermoid carcinoma	A431‡	51.12	49.44 (0.97)				

The binding assays were carried out in duplicate as described in Fig. 1 legend. All cells were grown in DMEM containing 10% calf serum except the melanoma S91M3 cells, which were grown in Dulbecco's modified Eagle's medium (DMEM) containing 15% horse serum and 2.5% fetal calf serum. All cells were treated for 5 days with 10^{-5} M retinoic acid (RA) or with ethanol in the control and were at equal density (5×10^5 cells per 35-mm dish) at the time of the binding assay. The specificities of the ligands used were: ^{125}I -labelled mouse EGF 0.825 ng ml^{-1} (9.5×10^4 d.p.m. per ng) was added, with $10 \mu\text{g}$ of unlabelled EGF to correct for nonspecific binding; ^{125}I -labelled Con A (NEN) 25 ng ml^{-1} (9.8×10^5 d.p.m.) and 15 mg ml^{-1} of α -methyl-D-mannoside to correct for nonspecific binding; ^{125}I -labelled insulin (Sigma) 2.5 ng ml^{-1} (2.7×10^5 d.p.m.) and $20 \mu\text{g ml}^{-1}$ unlabelled insulin to correct for nonspecific binding. The relative binding (binding of ^{125}I -labelled ligand to retinoic acid-treated cells/binding to control cells) is given in parentheses.

*Obtained from Dr T. Kakunaga; †obtained from Dr. N. Colburn; ‡obtained from Dr G. J. Todaro.

Table 3 Comparison of the action of retinoic acid and TPA on the binding of EGF to 3T6 and 3T12 C1A cells

Cell line	Treatment	^{125}I -EGF binding (pg per 10^6 cells)	Relative binding
3T6 (grown in the presence of 0.15% ethanol)	Control	87.0	1.0
	+TPA, 5 h	4.8	0.06
3T6 (grown in the presence of 10^{-5} M RA for 5 d)	Control	443.9	5.10
	+TPA, 5 h	77.7	0.89
3T12 CLA (grown in the presence of 0.15% ethanol)	Control	34.1	1.0
	+TPA, 5h	5.4	0.16
	+RA, 5 h	48.4	1.42
	+RA, 24 h	93.5	2.74
	+RA, 48 h	131.7	3.86
3T12 CLA (grown in the presence of 10^{-5} M RA for 5 d)	+TPA, +RA, 5 h	5.6	0.16
	Control	175.6	5.15
	+TPA, 5 h	86.5	2.54

Cells were treated with 100 ng ml^{-1} TPA and with 10^{-5} M retinoic acid (RA) at the times indicated. Controls received identical amounts of dimethyl sulphoxide or ethanol. EGF binding was assayed as described in Fig. 1 legend, EGF concentration was 1.25 ng ml^{-1} (1.1×10^5 d.p.m. per ng).

the binding of EGF. Cells grown for 5 days in the presence of retinoic acid also exhibit a reduced binding on TPA treatment, although this decrease is relatively smaller than in control cells. Thus, retinoic acid poorly antagonises the effect of TPA on EGF binding. Similar results were obtained for two epidermal cell lines, JB-6 and T62 (L.D. Dion and A.M.J., unpublished results). The above results seem to indicate an essential difference between the mode of action of retinoids and phorbol esters on EGF receptors: the slow action of retinoids on the cell surface seems to involve metabolism and/or macromolecular syntheses whereas the rapid action of phorbol esters may reflect conformational changes induced by alterations in the fluid state of the membrane²².

We have shown recently that retinoic acid stimulates differentiation of embryonal carcinoma cells PCC4 aza 1R (refs 12, 13). During 24–48 h of treatment with retinoic acid these

cells differentiate irreversibly into a cell type with a fibroblastic morphology. The differentiated cells can be distinguished from the original embryonal carcinoma cells by a variety of cell-surface markers¹². The PCC4 aza 1R cells exhibit very low levels of EGF binding whereas the differentiated derivative PCC4 D shows much higher levels of binding (Table 4). Therefore, EGF binding can be used as a marker to monitor differentiation of PCC4 aza 1R cells. After 24 h of treatment with retinoic acid, EGF binding increases concomitantly (not shown) with the appearance of cells with a fibroblastic morphology and the production of plasminogen activator which was used previously to monitor differentiation of PCC4 aza 1R cells¹². Similar results were recently reported for other embryonal carcinoma cell lines²³. The phenyl analogue of retinoic acid, which is unable to stimulate differentiation of embryonal carcinoma cells, has no stimulatory effect on EGF binding.

Thus, retinoic acid treatment of several cell lines enhances the binding of mouse EGF to its receptors, not by changing its affinity but by increasing the number of available receptor sites. Stimulation of EGF binding may result from an increase either in total receptor sites or in the number of unoccupied sites alone. Certain cell lines are known to produce endogenous growth factors²⁰, some of which may bind to the EGF receptor;

Table 4 Increase in EGF binding during differentiation of embryonal carcinoma cells PCC4 aza 1R induced by retinoic acid

Cell line	Treatment	^{125}I -EGF binding (pg per 10^6 cells)
PCC4 aza 1R	Control	1.2
	24 h RA	1.4
	48 h RA	20.3
	72 h RA	58.9
	96 h RA	112.7
	96 h ethanol	1.5
PCC4 D	96 h phenyl analogue	1.3
	Control	67.1
	96 h RA (10^{-5} M)	143.4

Cells were grown in DMEM containing 10% fetal calf serum. Differentiation was induced by the addition of 10^{-6} M RA or ethanol in the control. EGF binding was determined at the time intervals indicated, 1 ng EGF per ml (1.2×10^5 d.p.m.) was used. PCC4 D is the differentiated derivative obtained from PCC4 aza 1R after cloning¹¹.

retinoids may suppress the production of these factors leading to an increase in the number of unoccupied receptors and decreased cell growth. Alternatively, retinoids may increase the synthesis of EGF receptors. The implications of the increase in EGF receptor for cell growth remain to be established. Preliminary results show that EGF can enhance mitotic activity in serum-starved retinoic acid-treated cells, indicating that retinoids do not totally block the EGF response²⁶.

The action of retinoids on EGF binding provides us with a tool for studying the involvement of retinoid metabolites, like mannosylretinyl phosphate^{1,7}, in glycosylation of glycoproteins and a fast screening test for retinoids potentially active in inhibiting carcinogenesis^{24,25}.

I thank Dr Luigi M. De Luca, in whose laboratory this work was carried out, for his support and comments on the manuscript, Dr L. D. Dion for his comments on the manuscript and Dr Beverly A. Pawson (Roche) for providing the retinoid analogues.

Vitamin C preferential toxicity for malignant melanoma cells

Stanley Bram*†, Patrick Froussard*, Marcelle Guichard†, Claude Jasmin*, Yvette Augery*, Françoise Sinoussi-Barre‡ & Wayne Wray§

§ Baylor University Medical School, Houston, Texas 77030

Vitamin C has been suggested^{1,2} and disputed³ as an anti-cancer agent. For cells in culture, no preferential effect against any type of cancer has yet been demonstrated. Our aim here is to show that vitamin C is selectively toxic to at least one type of malignant cell—a melanoma—at concentrations that might be attained in humans. Copper ions react with ascorbate and generate free radicals in solution⁴. Ascorbate when combined with copper rapidly reduces the viscosity of DNA solutions and has exhibited some carcinostatic effects on transplanted sarcoma 180 tumours in mice⁵. We reasoned that the elevated copper concentration in melanoma^{6,7} could result in a more selective toxicity for ascorbate.

Fig. 1 A typical experiment on two melanoma and one normal cell line determining the reduction in the number of colonies by ascorbate only (●); or ascorbate + 5 μ M copper (○). Colony formation, which directly measures reproductive death, was carried out as previously described⁸. Briefly, about 200-500 single cells were inoculated into culture boxes and the number of colonies containing more than 50 cells was counted 8-14 days later. Colony-forming efficiency of parallel controls ranged from 25 to 60% for the different cell lines studied with this technique.

Inhibition was obtained from:

$$\frac{\text{No. of untreated control colonies} - \text{No. of treated colonies}}{\text{No. of untreated control colonies}}$$

Each point represents the average of a triplicate determination.

Cells (see Table 1) were grown in McCoy's medium supplemented with 15% fetal calf serum and antibiotics. Cytotoxic effects were determined using three independent techniques with parallel simultaneous runs on a melanoma and a non-melanotic cell culture (see Fig. 1). Drugs were added to cells 16-24 h after inoculation with single cell suspensions. Sodium ascorbate (Sigma) was added to cells from a water stock solution within 2 h of preparation.

Table 1 summarises the results obtained on 13 cell lines in four different laboratories. The concentration of ascorbate which resulted in a 50% decrease in colony formation, cell number or viability was between 0.2 and 0.5 mM (a mean of 0.3) for all the melanotic cell cultures studied. Cloned cell lines with many trypsinisations were as sensitive as cells recently put into culture. No obvious difference relating to the degree of pigmentation was noted. Ascorbate was added to Na11 cells which were suspended in agar⁸ 30 min after trypsinisation, and in another instance 30 h after inoculating into a Falcon box, yet the differences in the ID₅₀ were not significant. Plots of percentage inhibition with the three measuring techniques used not only gave similar ID₅₀ concentrations, but also exhibited a very sharp increase in inhibition at about this value (Fig. 1).

The non-melanoma cells tested (Table 1) were less sensitive to ascorbate and these other cell types exhibited a much larger range in their ID₅₀ values. Only mouse embryo fibroblast cultures showed an ascorbate sensitivity approaching that of melanoma cells.

A catalytic concentration of copper (5 μ M or ~ 20 less than the Cu²⁺ ID₅₀) increased ascorbate toxicity for melanoma two- to fivefold (Table 1). Cytotoxicity to other cells increased only 0 to 1.5 times.

Table 1 Effect of ascorbate on the growth of melanoma and other cells

g.i., Growth inhibition measurements were carried out by inoculating 10⁵ cells into 25-cm² boxes (Falcon). Drug exposures from 2 to 5 days with one to four ascorbate additions were studied. Results shown were obtained by addition of ascorbate 1 day after inoculation and by trypsinising and counting cells in a haemocytometer on day 5. Per cent inhibition was calculated from the equation in Fig. 1 using the number of cells counted.

c.f., Colony formation as described in Fig. 1.

c.f.a., colony formation in agar was carried out as by Salmon *et al.*⁸

t.b., Trypan blue exclusion (0.2%) and cell morphology were determined 5 days after one drug addition to about 1,000 cells in Falcon microwell plates. Viability determinations were done each in triplicate.

* Average value calculated from curves like those in Fig. 1.

^{1,2,3}, The number of independent experiments, each performed in duplicate or triplicate.

a, Cells from Dr B. Giovannella; b, see ref. 9 for further details; c, cells from Dr N. Saal; d, cells put into culture in September 1979 from normal adult skin; e, cells from Flow Laboratories; f, C₃H cells from Dr R. H. Bassin.

The results can be described as follows: melanoma cells were 2–10-fold and 5–20-fold, respectively, more sensitive to ascorbate, and to ascorbate plus 5 μ M Cu²⁺ than for amelanotic cells. Referring to the typical inhibition curves of Fig. 1, it can be seen that in 0.6 mM ascorbate the ability of melanoma cells to form colonies is 10 to 20 times less than for normal human amniotic cells. In 1 mM ascorbate no melanoma colonies were observed, while ~300 colonies were counted in controls; yet, at this concentration amniotic cell colony formation was inhibited by only 50%. The ratio of relative inhibition is then ~100-fold here.

With the exception of melanoma, no obvious difference between transformed (malignant) cell lines and normal cells was observed (Table 1). Copper ions alone exhibited some preferential toxicity to melanoma cells. On the other hand, the sensitivity to Cu²⁺ varied greatly from one cell line to another (Table 1), and non-transformed human amniotic cells were killed by lower concentrations of copper than many pigment cells.

The inhibitory effect of copper as sulphate, gluconate and acetate salts was studied. Although the pH of the stock 0.1 M solution added varied from 3.5 with copper sulphate to 5.3 with copper acetate, no difference in the Cu²⁺ ID₅₀ for melanoma cells was observed. Ceruloplasmin, the usual serum transport protein for copper, was not toxic to either melanoma or amniotic cells in the range 10–100 μ g ml⁻¹. However, in a preliminary study, both 7 \times 10⁻⁵ M ascorbate and 30 μ g ml⁻¹ of ceruloplasmin caused a 50% inhibition in colony formation.

Note that the relative growth inhibition of vitamin C for melanoma compared to normal cells at 5 \times 10⁻⁴ M (Table 1) is similar to that reported for vitamin A at 10⁻⁵ M (ref. 10). However, vitamin C is about 1,000 times less toxic than vitamin A.

The only previous report of ascorbate toxicity on melanoma cells was part of a study of the killing effect of dopa and other melanin precursors¹¹. Our results confirm the finding¹¹ that ascorbate reduces the toxic effect of dopa. The pertinent result mentioned in ref. 11 was that 1 mM ascorbate reduced thymidine incorporation in Cloudman S-91 cells by 33% after a

16-h exposure. We obtained a similar inhibition with a 16-h exposure. In our experiments we have found that cytotoxic effects at 2–4 \times 10⁻⁴ M ID₅₀ concentrations of ascorbate become evident only after about 48 h. For non-melanoma cells, our ID₅₀ of 1–2 mM for human amniotic, HeLa, and CHO cultures compares well with values in the literature (Table 2). Vitamin C and copper are required for melanin biosynthesis, and are preferentially incorporated by melanoma tissues^{6,7,16}, yet, at elevated concentrations, both of these agents inhibit dopa oxidase activity^{17,18}. This is one possible mechanism for the specific inhibition of melanoma cell proliferation.

Nonspecific ascorbate toxicity has been attributed to the formation of H₂O₂ during its auto-oxidation^{14,19}, but at pH < 7.6 ascorbate is no longer auto-oxidisable except in the presence of metallic catalysts such as copper¹³. Ascorbate has little or no antimicrobial activity in the absence of metal ions⁴. A cogent example from the early literature is that 6 \times 10⁻⁵ M ascorbate plus 5 μ M Cu²⁺ completely inactivated polio virus after a 4-h contact⁴, while in the presence of EDTA, 6 \times 10⁻⁴ M ascorbate had no effect. Thus it seems reasonable to suggest that the selective toxicity of ascorbate for melanoma is partly due to preferential incorporation of copper. That catalytic concentrations of Cu²⁺ greatly increase the preferential toxicity of ascorbate for melanoma cells, suggests that an intracellular mechanism is involved here.

A likely target for ascorbate killing is DNA. Mutagenic properties of ascorbate and copper have been demonstrated on

Table 2 Ascorbate inhibition

Cell types	Approximate ID ₅₀ (mM)	Refs
Rat plasmacytoma	1.5*	12
Mouse neuroblastoma	1.5*	13
Mouse glioma	2*	13
Ehrlich ascites	10†	14
Chinese hamster V 79	4†	15

* An exposure to ascorbate for more than 36 h was used as in Table 1.

† An exposure of less than 4 h was used.

bacteria and bacteriophage^{21,22} and more recently on eukaryotic cells²³. Vitamin C and copper rapidly eliminate the replication and virulence of bacteria (that is, *Bacillus pestis* of bubonic plague), but do not alter neither morphology antigenicity, or most biochemical reactions over a much longer period of time²¹.

Ascorbate rarely acts as a coenzyme or vitamin but generally modifies the redox potential of the cell. Vitamin C can thereby appreciably potentiate or deactivate many antitumour drugs¹³.

The results presented here indicate that vitamin C may directly inhibit the growth of proliferating cells, and this might explain some of the reported carcinostatic effects². Such an inhibition would depend on the extent to which a given cell incorporates ascorbate, and the sensitivity of the cell to its

cytotoxic effects. Melanoma cells have been found to preferentially incorporate vitamin C (ref. 16), and our *in vitro* studies show that vitamin C is more toxic to melanotic cells than to any others studied so far.

Saturation levels of ascorbate in tissues range from 1 to 2 mM (ref. 24). Such concentrations in our experiments inhibit malignant melanoma cells 20 to 500 times more than the other cell studied. Moreover, as 10^{-5} M free copper concentrations are not toxic in man, the synergistic effect of copper on ascorbate can also be exploited. *In vivo* experiments on mice with melanoma are under way, and clinical studies are planned.

We thank Drs E. Malaise and J. C. Chermann for suggestions and Dr B. Giovannella for his gift of cell lines. Financial support was provided by the CNRS, INSERM and the DGRST.

Vasopressin increases water permeability by inducing pores

Stephen Gluck & Qais Al-Awqati

Departments of Medicine and Physiology, Columbia University, College of Physicians and Surgeons New York, New York 10032

Vasopressin is thought to increase the water permeability of the luminal membrane of distal urinary epithelia either by enhancing the solubility or diffusion of water in the lipid phase¹ or by inducing aqueous pores². Measurement of the permeability to water and small solutes in different experimental conditions should allow the distinction between these two modes of water transport^{1–9}, but because of technical difficulties (for instance the effect of unstirred layers^{3–6}) or conceptual problems (in the case of activation energy measurements^{7–9}) the interpretation of many of these methods is in question. We present here a new approach to this problem using proton conductance of the membrane as a probe for the presence of aqueous channels. Protons travel in free solution by jumping from one water molecule to another¹⁰. If vasopressin induces aqueous pores, it should also increase proton permeability, as protons will be able to jump from a water molecule in the bulk solution to another in the pore. However, if vasopressin changes water permeability by increasing membrane fluidity the proton conductance should not increase as the dielectric constant of even very fluid lipids is low, leading to extremely low solubility of ions in the lipid¹¹. We found that vasopressin increased the proton permeability of the luminal membrane of the toad urinary bladder and conclude that this hormone increases water permeability by inducing aqueous pores rather than by increasing lipid fluidity. Proton conductance may be of use in determining the existence and properties of other aqueous channels.

Vasopressin increased the proton disappearance from an acid mucosal medium bathing Dominican toad bladders, an epithelium which does not actively transport protons (Fig. 1). In 22 experiments vasopressin increased the proton permeability (G_H) by $7.24 \times 10^{-4} \text{ cm s}^{-1}$, a 300% increase.

To investigate the site of the vasopressin-induced proton conductance we measured the intracellular pH using the distribution of the weak acid, dimethyl-oxazolidine-dione

(DMO)¹². Paired bladders treated with vasopressin were placed in a solution containing ^{14}C -DMO and ^3H -inulin at pH 7.4 for 1 h. The mucosal solution of one member of each pair was replaced by a medium of pH 5.0 containing the same concentration of ^3H -inulin and an amount of ^{14}C -DMO calculated to give the same concentration of the free-acid DMO (~4% of the original DMO concentration). After 15 min, the

Fig. 1 Effect of vasopressin on H^+ movement across toad bladder. Bladders were placed in Ussing chambers, in short-circuit conditions, using a bicarbonate-free low buffer medium and rates of proton disappearance from the mucosal medium were measured by titration. The figure shows one experiment. Addition of vasopressin to the serosal medium markedly increases the rate of proton disappearance within a few minutes. When the pH reaches 5.1 a measured quantity of acid is added to the luminal medium serving to calibrate proton disappearance and to return the pH to 5. To demonstrate that the proton flux induced by vasopressin results from flow across the epithelium rather than from buffering at the surface, we showed in six experiments that the short circuit current in the presence of amiloride (which abolishes the sodium current) is not different from the simultaneously measured mucosal proton disappearance (0.42 compared with $0.36 \text{ nmol cm}^{-2} \text{ min}^{-1}$). Further, the mucosal proton disappearance and serosal proton appearance in the same bladders were equal (0.34 and $0.33 \text{ nmol cm}^{-2} \text{ min}^{-1}$, $n = 3$).

Fig. 2 Plot of the simultaneously measured changes in proton permeability (G_H) and $^3\text{H}_2\text{O}$ permeability (P_D) induced by vasopressin. The proton permeability was measured as the ratio of the flux to the concentration difference.

intracellular pH of scraped epithelial cells from the control bladder was 6.7 while the pH of those exposed to the low mucosal pH was 6.12 ($\Delta\text{pH} = 0.55 \pm 0.12$, $n = 6$). This suggests that the vasopressin-induced proton permeability occurs at the mucosal border of the cell. Further evidence for this was obtained from measurement of the effect of amiloride on H^+ fluxes in the presence of vasopressin. Amiloride increases the negative potential of the toad bladder epithelial cell and hence should increase the electrical gradient for proton movement into cells¹³ while having no effect on the paracellular conductance. In 10 experiments in vasopressin-treated toad bladders, addition of amiloride to the luminal medium increased the proton flux by $0.06 \pm 0.03 \text{ nmol cm}^{-2} \text{ min}^{-1}$ ($P < 0.05$). These results demonstrate that vasopressin increases the proton permeability of the luminal border of toad bladder cells, rather than the permeability of the paracellular pathway.

Simultaneous measurement of G_H and tritiated water permeability (P_D) showed that the increase in G_H correlated with the increase in P_D , $r = 0.947$, $n = 6$ (Fig. 2). Since vasopressin increases the urea and sodium permeability as well as water permeability, we investigated whether protons move through urea or sodium channels. Methohexital, an anaesthetic that inhibits vasopressin-induced water permeability but has little effect on urea and sodium permeabilities¹⁴, reduced the vasopressin-induced proton permeability from $5.80 \times 10^{-4} \text{ cm s}^{-1}$ to $1.44 \times 10^{-4} \text{ cm s}^{-1}$ ($P < 0.01$, $n = 9$). Two results suggest that the protons are not crossing urea channels. We found no correlation between ^{14}C -urea and proton permeability measured in 10 bladders. Furthermore, addition of phloretin, an agent which inhibits urea transport without affecting water permeability¹⁵, abolished the vasopressin-induced urea permeability (control $9.92 \times 10^{-4} \text{ cm s}^{-1}$, 0.1 mM phloretin $0.26 \times 10^{-4} \text{ cm s}^{-1}$, $P < 0.01$, $n = 6$ paired hemibladders) but had no significant effect on the proton permeability measured in the same bladders (control $2.60 \times 10^{-4} \text{ cm s}^{-1}$, phloretin $1.86 \times 10^{-4} \text{ cm s}^{-1}$). It is not likely that protons cross sodium channels as the effect of vasopressin on sodium transport was transient while its effect on proton permeability was not; 30 min after addition of vasopressin the proton flux was 561% above the initial rate while sodium transport was only 25% above the initial value ($n = 14$). Also, as shown above, amiloride abolished sodium transport but increased the proton flux in the presence of vasopressin.

Since protons, being small ions, cannot pass through even very fluid lipid membranes, the above results show that vasopressin must have induced aqueous channels which conduct protons. A rough estimate of the conductance of these channels can be obtained by comparing their proton to water permeability ratio to that of gramicidin A channels. The proton conductance of a single gramicidin A channel at pH 5.0 is 0.015 pS (ref. 16) and its P_D $1.8 \times 10^{-15} \text{ cm}^3 \text{ s}^{-1}$ (ref. 17), giving a ratio of 7.8 S s cm^{-3} . The vasopressin induced proton conductance was $3.22 \mu\text{S cm}^{-2}$ and the P_D increased by $0.78 \times 10^{-4} \text{ cm s}^{-1}$, giving a ratio of

0.04 S s cm^{-3} . The vasopressin-induced channels are at least 200 times less conductive than gramicidin A. Whether this is due to their native ion selectivity or to a very low density of water or to other factors remains to be determined.

A novel α -globin gene arrangement in man

D. R. Higgs, J. M. Old, L. Pressley, J. B. Clegg & D. J. Weatherall

MRC Molecular Haematology Unit, Nuffield Department of Clinical Medicine, John Radcliffe Hospital, Headington, Oxford OX3 9DU, UK

The human genome has two linked α -globin genes on chromosome 16. Deletion of one or more of them, as occurs in α -thalassaemia, leads to a reduced output of α -globin mRNA in proportion to the number of α -globin genes lost¹. In some racial groups deletion of one of the pair of α -globin genes may result from unequal crossing over between the genes on homologous chromosomes^{2,3} by a mechanism resembling that postulated for the formation of the $\delta\beta$ fusion genes of the Lepore haemoglobins⁴. By analogy, the opposite chromosome in this cross-over should have three α -globin genes just as the 'anti-Lepore' chromosome has three non- α -chain genes. We describe here a Welsh family in which three members have five α -globin genes—three on one chromosome and two on the other. The additional α gene results in an increased α mRNA output and it may therefore produce the phenotype of mild β -thalassaemia.

DNA was obtained from a 61-yr-old male (E.J.) and his sons (D.J., R.J. and C.J.). Two of the sons (D.J. and C.J.) were subsequently shown to have the same α -globin gene arrangement as their father whereas R.J. had a normal α -gene arrangement. Digestion of normal DNA with the endonucleases *Bam*HI and *Eco*RI, or a combination of the two, generates a single fragment containing both α -globin genes^{2,5,6}. When DNA from E.J. was digested with these enzymes two fragments were obtained, one of normal size and the other consistently 3.5–4.0 kilobases larger (Fig. 1A). This result suggested that E.J. has one chromosome which yields a normal restriction fragment and another which produces a larger fragment with an insertion of approximately 3.5–4.0 kilobases of DNA between the *Eco*RI and *Bam*HI restriction sites which surround the two α -globin genes.

Digestion of normal DNA with *Bgl*II or a combination of *Hpa*I and *Eco*RI generates two α -specific fragments, as these enzymes cut outside and between the two α genes (Fig. 1A, B) (refs 2, 6 and E. Whitelaw, personal communication).

When E.J. DNA was digested in this way the two normal bands were present and of equal intensity, but in addition, in each case a third less intense band, 3.7 kilobases long, was produced. This fragment must have been derived from a third α

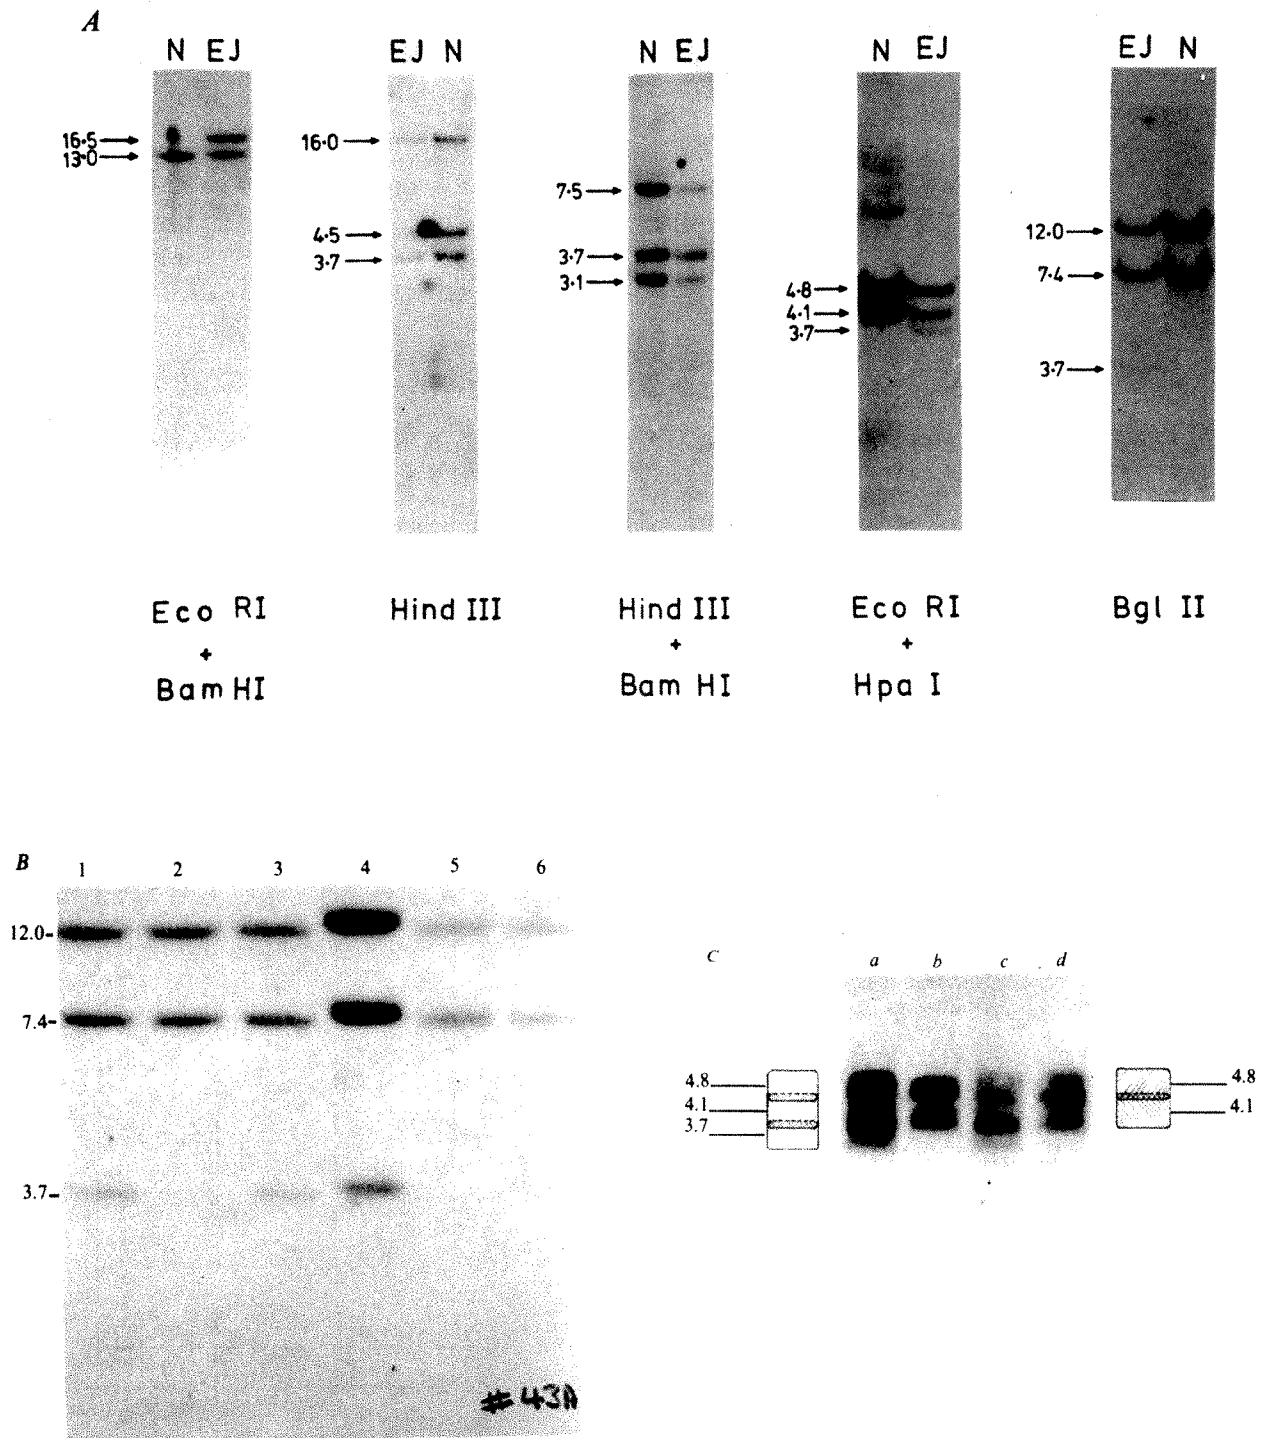

Fig. 1 A, Autoradiographs of DNA obtained from E.J. digested with various restriction enzymes. The sizes of DNA fragments are represented in kilobases. DNA was obtained by phenol chloroform extraction of peripheral blood or bone marrow⁹. Following restriction of 20 µg of DNA with 0.5–2.0 units of enzyme per µg DNA the samples were electrophoresed in 0.8% agarose and then transferred to nitrocellulose filters¹⁰. The DNA on the nitrocellulose filters was then hybridised to an α plasmid JW101 (ref. 11) which had been nick translated by the method of Maniatis *et al.* using ³²P-dCTP and ³²P-dATP (Radiochemical Centre) as radioactive labels¹². The filters were then washed in stringent conditions² and autoradiographed using Fuji-RX-X-ray film according to the method of Lasky and Mills¹³. An additional band (~10 kilobases) is present in the autoradiograph of the *Eco*RI/*Hpa*I double digest of normal DNA, representing an incomplete digest of the DNA which, in this case, was present in a greater amount than usual for such a digest. A faint (3.7 kilobase) band is present in the autoradiograph of the *Bgl*II digest of E.J. DNA in A. However, this band is clearly shown in B, lane 4. B, Autoradiographs of DNA obtained from D.J. (1), R.J. (2), C.J. (3), E.J. (4), normal (5), normal (6), which had been digested with *Bgl*II. The same pattern, consistent with the genotype $\alpha\alpha\alpha/\alpha\alpha$, was present in DNA from E.J., D.J. and C.J. The intensity of the normal fragments compared with the new 3.7-kilobase fragment is approximately 2:1, which is the ratio predicted for this gene arrangement. C, Autoradiograph of fragments produced by *Hpa*I digestion of DNA isolated from the abnormal 16.5-kilobase fragment generated by cleavage of E.J. DNA with a combination of *Eco*RI and *Bam*HI as described in the text. The 13-kilobase fragment (channels b, d) produced two α -gene fragments 4.8 and 4.1 kilobases long, whereas the 16.5-kilobase fragment produced three α -specific fragments of 4.8, 4.1 and 3.7 kilobases (channels a, c). The bands produced in these autoradiographs are broader than normal because when the samples, which were cut out from the low-melting temperature agarose, had been restricted and then re-applied to agarose gel, the DNA was in a larger volume than is conventionally applied to agarose gel for electrophoresis.

Haematological and haemoglobin analysis was carried out using standard techniques⁷. All haematological studies were carried out on two separate occasions, with good agreement between duplicate results. E.J. had an unrelated haematological malignancy and therefore all studies were carried out on his haematologically normal sons R.J., D.J. and C.J. RBC, Red blood cell count; Hb, haemoglobin; Hct, haematocrit; MCV, mean corpuscular volume; TIBC, total iron-binding capacity; SA, specific activity.

gene present in the inserted DNA of the abnormal chromosome, with *Hpa*I and *Bgl*II sites 3.7 kilobases from their respective sites in the normal sequence between the two genes (Fig. 2). *Hind*III cuts normal DNA to the right and left within the α -globin genes^{2,5,6} to produce three fragments of 16, 4.5 and 3.7 kilobases. The 16- and 4.5-kilobase fragments are cleaved by *Bam*HI to yield 7.5- and 3.1-kilobase fragments, respectively. Digestion of E.J. DNA with *Hind*III generated only the three normal fragments (Figs 1A, 2). The 16- and 4.5-kilobase *Hind*III fragments were both cleaved by *Bam*HI to yield normal-sized fragments. The *Bam*HI sites on either side of the two α -globin genes are thus positioned normally, and a new *Hind*III site exists inside the inserted DNA sequence, giving rise to a new fragment 3.7 or 4.5 kilobases long and therefore indistinguishable from the normal *Hind*III fragments. The positions of the *Hpa*I, *Bgl*II and *Hind*III sites indicate that the inserted DNA is a repeat of intergenic DNA and an α -globin gene. A similar conclusion was drawn from a double digest of E.J. DNA with *Hpa*I and *Hind*III; four fragments were observed, all corresponding to those found in normal DNA⁶.

In Fig. 2, the α -gene fragments generated by various restriction enzymes are compared with those from a normal chromosome. Although all the abnormal fragments can be generated from an abnormal chromosome without a third α -globin gene locus in the inserted

DNA, the intensity of the autoradiograph bands in the *Bgl*II digest and the *Eco*RI/*Hpa*I digest suggested that the abnormal chromosome does contain a third α -globin gene. In both digests, band intensities agree with the normal to abnormal band ratio of 2:1 predicted in Fig. 2.

Finally, E.J. DNA was digested with *Eco*RI plus *Bam*HI and the products fractionated in a low-melting temperature agarose gel. The large 16.5-kilobase fragment was separated from the normal 13.0-kilobase fragment by slicing the gel between and outside the calculated band positions. Both DNA fragments were redigested with *Hpa*I and fractionated in a normal agarose gel. The 13.0-kilobase fragment produced two α -gene fragments of 4.8 and 4.1 kilobases as expected. However, the

Fig. 2 The gene arrangement in E.J., C.J. and D.J. with two α genes on one chromosome and three on the other. The fragment sizes obtained from each chromosome following digestion with various restriction enzymes are shown below. The dotted lines indicate that the new arrangement contains an exact repeat of intergenic DNA and an α -globin gene. An identical map would be obtained if the inserted gene were placed to the right or left or between the normal duplicated α genes. The critical point is not the exact location of the inserted DNA but that it repeats precisely a part of the normal duplicated α -gene arrangement. As two fragments of equal size and one new fragment 3.7 kilobases long are produced by the enzyme *Bgl*II or a combination of *Hpa*I and *Eco*RI, the relative band intensity of 2:1 would be predicted from this model.

Fig. 3 α/β mRNA ratios in R.J. (■) and C.J. (●) compared with those of individuals with 4 (normal), 3 (α -thalassaemia 2; α thal 2), 2 (α -thalassaemia 1; α thal 1) and 1 (haemoglobin H disease; Hb H disease) functional α -globin genes. α/β mRNA ratios were determined as previously described¹. The range of α/β mRNA ratios in normal individuals was 2.0–2.45. This range of α/β -specific RNA sequences in the cells of normal individuals is higher than those previously reported and the significance of this is discussed elsewhere¹. However, the importance of these results does not lie in the absolute values obtained for α/β -specific sequences but rather the relative values in the various α -thalassaemia syndromes. The α/β mRNA ratio in C.J. with the arrangement $\alpha\alpha\alpha/\alpha\alpha$ was about 20% higher than normal and falls within the range that would be predicted by extrapolation from the other groups if there was no compensation in the transcription of mRNA in individuals with five α -globin genes.

16.5-kilobase fragment produced three α -gene fragments of 4.8, 4.1 and 3.7 kilobases (Fig. 1C), proving conclusively that the abnormal chromosome contains three α -globin gene sequences instead of two. Such a situation would arise if the abnormal chromosome had arisen by an unequal crossing over

Fig. 4 α/β globin synthesis ratios in C.J. (●), D.J. (▲) and R.J. (■) compared with those individuals with varying numbers of functional α genes; α/β globin chain synthesis ratios were obtained as previously described¹⁴. The ratios obtained in 24 haematologically normal individuals, 11 subjects with α -thalassaemia 2, 7 subjects with α -thalassaemia 1, and 13 subjects with Hb H disease are shown. The ratios obtained in C.J., D.J. and R.J. are the average of two ratios obtained on separate occasions (Table 1) and fall within the range found in normal individuals.

between the α -globin genes, as proposed for the origin of the α -thalassaemia 2 genotype in several racial groups^{2,3}.

Haematological studies on D.J., C.J. and R.J. showed them to be normal (Table 1). Recently, α/β mRNA ratios in individuals with 4, 3, 2 and 1 functional α genes have been shown to fall into four non-overlapping groups¹. In R.J., who had the globin gene arrangement, $\alpha\alpha/\alpha\alpha$, the α/β mRNA ratio fell within the normal range (Fig. 3). However, in C.J., who had the $\alpha\alpha\alpha/\alpha\alpha$ globin gene arrangement, the α/β mRNA ratio was 20% higher than normal. Thus, it seems that when five α -globin genes are present, each is fully expressed at the mRNA level and there is no compensatory reduction in α mRNA output. However, the average α/β globin chain synthesis ratios in C.J. fell within the normal range (Table 1, Fig. 4).

Normal red cell precursors produce a slight excess of α chains, which are removed by proteolysis to achieve balanced α/β globin synthesis⁷. The fact that individuals with five α genes are haematologically normal and have no overall globin chain imbalance indicates that their red cell precursors can effectively compensate for an even greater excess of α -globin chain synthesis. However, the additional α gene might not always be functionally unimportant. Some cases of β -thalassaemia are unusually mild and there is genetic evidence that they are, in fact, compound heterozygotes for β -thalassaemia and 'silent β -thalassaemia', so called because it is not detectable in simple heterozygotes⁸. It is possible that some of these silent β -thalassaemias are, in fact, examples of the $\alpha\alpha\alpha/\alpha\alpha$ or $\alpha\alpha\alpha/\alpha\alpha\alpha$ genotype. Furthermore, one would predict that the basic thalassaemic nature of this genotype will only be revealed through its interactions with β -thalassaemia or β -chain haemoglobinopathies, such as Hb S.

This work was supported by the MRC. D.R.H. holds an MRC Training Fellowship. We thank Mrs H. Ayyub and Mrs B.

Aldridge for technical assistance, Dr B. Forget for plasmid JW101, and Dr C. Barton for bringing this family to our attention.

Note added in proof: Since this paper was submitted similar findings have been reported in individuals of Mediterranean background¹⁵.

Coordinately expressed members of two chorion multi-gene families are clustered, alternating and divergently orientated

C. Weldon Jones & Fotis C. Kafatos

Cellular and Developmental Biology, Biological Laboratories, Harvard University, Cambridge, Massachusetts, 02138

The chorion (eggshell) of silkmoths consists of more than 100 distinct proteins. Individual components are synthesised in characteristic and overlapping sequence, at early, middle, late or very late developmental periods of choriogenesis (which lasts 2 days in total)^{1,2}. Protein sequencing^{3,4} indicates that components which belong to two size classes, A and B, are encoded by two respective families of evolutionarily homologous genes (multi-gene families). Genetic analysis in *Bombyx mori*^{5,6} has shown that chorion genes are tightly linked in three clusters on a single chromosome ($n = 28$). Total chorion mRNA of the wild silkworm, *Antheraea polyphemus*, has been copied into double-stranded cDNA and cloned by recombinant DNA procedures⁷. Many distinct cDNA clones have been selected and identified as members of the A and B multi-gene families by detailed cross-hybridisation⁷ and sequencing⁸ analysis. Stringent conditions which minimise cross-hybridisation permit use of these clones as specific probes. In many cases, we know the protein encoded and the developmental period when the clone sequence can be found in cytoplasmic RNA^{7,8}. Thus, we may now use these cDNA clones as probes to determine how genes of known developmental properties and evolutionary history are arranged within the chorion chromosomal region. We report here that two cloned, 14-kilobase chromosomal DNA segments contain multiple chorion genes. In each segment, the genes represent both A and B families, but only one developmental class: one segment contains only middle-period A and B genes and the other only late-period A and B genes. In both segments, members of the two families are arranged in alternating sequence and divergent orientation.

A library of *A. polyphemus* chromosomal DNA clones was established⁹, using the charon 4 derivative of phage λ as vector¹⁰. Screening of approximately 180,000 phage plaques with total chorion cDNA permitted selection of a 'bookshelf' of 175 independent chromosomal clones containing chorion genes. After plaque purification, these clones were spotted on lawns of

Escherichia coli strain CSH18 and re-screened¹¹, using as probes nick-translated, characterised cDNA clones. Chromosomal clones were selected which hybridised strongly with two non-cross-reacting cDNA clones, even in stringent conditions (80 °C and 0.45 M NaCl, or approximately 10 °C below T_m for that probe length). Clone APc110 hybridised with two late sequences: the A-family sequence, pc18, and the B-family sequence, pc401. By contrast, clone APc173 hybridised with two middle-period sequences: the A-family sequence, pc292, and the B-family sequence, pc10. This suggested that chorion genes are clustered according to the developmental period when they are expressed, rather than according to the multi-gene family to which they belong. Preliminary screening of the library with additional probes supported that suggestion (data not shown).

For detailed analysis of gene arrangements, restriction maps of APc110 and APc173 were constructed by standard procedures (Fig. 1). Blot-hybridisation¹² experiments revealed in

Fig. 1 Restriction maps of two chromosomal DNA clones from *A. polyphemus* carrying multiple chorion genes. Shading indicates the approximate location of genes numbered with reference to corresponding cDNA clones^{7,8}. Arrows show the direction of transcription. Clone APc110 contains only late-period genes, from two multigene families (pc18 = A; pc401 = B) and in opposite orientation. Clone APc173 contains only middle-period genes, again from two multi-gene families (pc292 = A; pc10 = B) and in opposite orientation. Locations of the genes were suggested by characteristic restriction sites known from the cDNA clones: *KpnI* for pc18, *SstI* for pc10, *KpnI* and *HindIII* for pc401, and *KpnI* and *SstI* for pc292. Confirmation came from detailed blot-hybridisation analysis using double enzyme digests. For example, the largest *KpnI* fragment of APc110 (~5.8 kilobases (kb)) contains both pc401 and pc18 sequences; after secondary digestion with *HindIII*, the left-most derivative (~3.6 kilobases) contains only pc401 sequences, the right-most derivative (~0.7 kilobases) contains only pc18 sequences, and the middle derivative (~1.5 kilobases) contains neither. Further confirmation came from blot-hybridisation experiments with 5'-specific or 3'-specific probes, which also defined the directions of transcription (see Fig. 2). One or more additional unmapped *SstI* sites exist between the two right-most *SstI* sites shown for APc173. Ba, *BamHI*; Bg, *BglII*; H3, *HindIII*; Kp, *KpnI*; St, *SstI*.

each case two non-contiguous copies of each of the represented cDNA sequences, in an alternating arrangement (BABA). Locations of the genes on the map were initially suggested by characteristic restriction sites known to be present in the clone cDNA sequences. These locations were verified by blot-hybridisation analysis of double enzyme digests (see Fig. 1 legend).

All four cDNA clones represented in these chromosomal segments have been sequenced. Thus, we could take advantage of centrally located restriction sites (*KpnI* for pc401 and pc18; *SstI* for pc10 and pc292) to generate probes representing either the 5' half or the 3' half of the corresponding mRNA. Blot-hybridisation of the chromosomal clones with these half-probes

defined the direction of transcription for each chromosomal gene (see, for example, Fig. 2). All experiments with half-probes gave a consistent directional map: A and B genes are transcribed in opposite orientations (arrows in Fig. 1), that is, A genes are transcribed from one DNA strand and B genes from the other.

The analysis with half-probes also established firmly that the blocks of each cDNA sequence represent two different gene copies, rather than one copy split in half by a very long intervening sequence. For example, in APc110, the pc401 half-sequences from left to right showed a 5'-3'-5'-3' progression, which is inconsistent with a single gene copy.

Fig. 2 Determination of transcriptional direction. The sequenced cDNA clones (ref. 8, unpublished observations, and S. G. Tsitilou, personal communication) were nick-translated and cleaved with *SstI* to generate separate probes specific for the 5' region or 3' region of each mRNA. Here blot-hybridisations of an *SstI* digest of APc173 are shown using such half-probes. The first track displays the ethidium bromide-stained total DNA pattern; arrowheads indicate DNA fragments which include chorion gene sequences (see the next four tracks), small dots indicate fragments which include moth DNA but no chorion sequences, and the unmarked fragments are derived solely from the chorion 4 vector. The blot-hybridisation patterns show that the 5' regions of both pc10 and pc292 are found in the same two fragments (1.5 and 1.7 kilobases), whereas both 3' regions are only found together in a third fragment (2.2 kilobases); the 3' regions of pc10 and pc292 are also found individually, in two fragments of approximately 21.0 and 1.25 kilobases, respectively. These results are only consistent with divergent orientation of the genes (arrows in Fig. 1).

Blot-hybridisations of the chromosomal clones with total chorion cDNA revealed no additional chorion genes other than those shown in Fig. 1. However, sequencing of the left-hand end of APc110 revealed the presence of a very short sequence corresponding to the 5'-untranslated region of another pc18 gene (data not shown). Thus, two divergent AB pairs are found in each chromosomal clone (18a, 401a; 18b, 401b; 10a, 292a; 10b, 292b). We suspect that the right-hand copy of pc18 (18c in Fig. 1) is indicative of a third pair in APc110. The pairs are not part of invariant repeats; for example, the two *KpnI* fragments which contain the 3' ends of genes are unequal in length (3.9 and 5.8 kilobases), and also differ in several restriction sites.

The genes represented in APc110 correspond to two of the most abundant chorion mRNA sequences¹³. Do additional copies of these genes exist in the genome, and if so, are all copies found as divergent AB pairs? Figure 3 provides affirmative answers to both questions. Total moth DNA was restricted with *KpnI* and blot-hybridised with 5'-specific or 3'-specific probes

Fig. 3 Detection and organisation of repeated chorion genes in the moth genome. Total DNA from pooled developing pupae was digested with *KpnI*, electrophoresed, transferred to nitrocellulose¹² and hybridised with 5'- or 3'-specific ³²P-probes consisting of *KpnI* fragments from nick-translated cDNA clones pc401 and pc18; each probe contained the appropriate half of the chorion cDNA insert plus contiguous plasmid sequence. Hybridisation was at 75 °C in 0.45 M NaCl. Two aliquots of moth DNA were used in each experiment (1×, 10 µg; 2×, 20 µg). Reconstruction standards were included to estimate the gene multiplicity. They consisted of increasing amounts of a *HindIII/KpnI* digest of a subcloned *HindIII* fragment from APc110 (containing the entire *18b* gene and the 5' half of the *401b* gene; see Fig. 1), plus 10 µg sheared calf thymus DNA; only the hybridising *HindIII* to *KpnI* moth DNA fragments are shown. Each standard corresponds to the indicated number of gene copies per haploid genome ($C = 1$ pg), relative to the 1× moth DNA sample. Two major genomic bands hybridise with both 5' probes (top). When a mixture of the two probes is used, again only two bands are seen, confirming that the 5' ends of both types of genes hybridise to the same fragments (data not shown). The lower band (2.1 kilobases; dot) is expected from the map of APc110 (*KpnI* fragment containing the 5' ends of *18b* and *401b*; Fig. 1). The upper band (2.5 kilobases) indicates the existence of a second type of linked and divergent *401/18* pair in *A. polyphemus*. The combined intensities of the two bands, in comparison with the standards, indicate the existence of approximately 15 ± 5 *401/18* gene pairs per haploid genome (the gene *18* estimate is more dependable in this respect, as probe, standard and genomic fragment are co-terminous, whereas the standard lacks 130 of the 300 base pairs of *401* sequence represented in both probe and genomic fragment). At very long exposures, faint hybridisation to additional high molecular weight bands can be seen with both probes, possibly indicating limited polymorphism, single copies of additional *401/18* pairs, or cross-hybridisation with different but similarly organised genes of the same multi-gene families^{7,8}. Hybridisations with 3'-specific probes (bottom) reveal multiple bands, only some of which are identical for the two genes. This indicates that heterogeneity beyond the 3' ends of the genes is much greater than between the 5' ends. The expected 3.9-kilobase fragment (between *401a* and *18b*; Fig. 1) is indicated by a dot; the expected 5.8-kilobase fragment (between *401b* and *18c*) is seen in long exposures, but is smeared because of localised overloading of the gel (it co-migrates with a large number of unrelated *KpnI* genomic DNA fragments).

from cDNA clones pc401 or pc18, together with reconstruction standards. From the intensities of the blots, we estimate that approximately 15 ± 5 copies each of the *18* and *401* genes exist per haploid genome. With the 5' probes, only two major fragments hybridise, and they are the same for both *401* and *18*. The more intense fragment (which is found in approximately 10 copies per genome) corresponds to what is expected from clone APc110, whereas the other is longer by 0.4 kilobases. As these fragments were generated with *KpnI*, which cleaves within both *401* and *18* genes, and as each fragment contains the 5' ends of both *401* and *18*, we conclude that the multiple copies of these two genes are present in the genome as divergent AB pairs.

The map of APc110 shows length and restriction site variability 3' to the genes. As might be predicted, multiple bands of genomic DNA hybridise with each 3' probe, and some of these are different for the two probes. This confirms that greater variability is found in the long DNA segments containing the 3' ends of the genes than in the short DNA segments containing the divergent 5' ends. We conclude that APc110, and presumably also APc173, are representative: the multiple copies of four major chorion genes are arranged in pairs, each pair containing, in divergent orientation, coordinately expressed members of two different evolutionary families.

The co-expressed H3-H4 and H2A-H2B histone genes in *Drosophila* are arranged as divergent pairs within a repeat unit¹⁴, whereas in sea urchins the repeat includes only tandemly orientated genes¹⁵. Genes for the 70,000 molecular weight heat-shock protein are clustered in two loci, *87A* and *87C*, and include both tandemly orientated and divergent copies^{16,17}. Three apparently co-expressed ovalbumin-like genes are clustered in a tandem orientation¹⁸. Mammalian β -like globin genes are found in tandemly orientated pairs, arranged in progression according to their temporal expression¹⁹⁻²¹. Analysis of human deletions has shown that the developmental switching-off of one globin gene pair is controlled by a sequence element many kilobases away in the 3' direction (but located 5' to the next gene pair)¹⁹. Thus, coordinately expressed gene clusters may not be uncommon for eukaryotes. The chorion clusters are reminiscent of the histone genes in that they involve more than one sequence family. Clustering of co-expressed genes apparently does not reflect polycistronic transcription, because in some cases the genes are divergent, and because even the tandemly orientated globin genes seem to be transcribed individually^{22,23}. Although alternative interpretations are possible, clustering may be related to a gross level of regulation, such as availability for transcription in a particular type of differentiated cell, or at a certain developmental stage or physiological state, as a result of localised unravelling of chromatin²⁴; a visible manifestation of such a process might be the heat-shock-induced puffing of the *87A* and *87C* loci²⁵, each of which contains more than one gene copy. By contrast, divergent orientation might be related to finer-level regulation, such as precise temporal or quantitative coordination. In prokaryotes, divergent gene clusters are controlled by centrally located *cis*-acting regulatory elements²⁶; in addition, bi-directionally acting regulatory genes have been demonstrated in both prokaryotes and eukaryotes, although the transcriptional orientation of the flanking genes subject to regulation is not always known (reviewed in refs 26-28). Divergent organisation of repeated genes may also have interesting evolutionary implications: it may be that the unit of expansion or contraction in these multi-gene families is the gene pair, rather than individual genes. Functional interpretation of the intriguing gene arrangement reported here must await investigation of the generality of its occurrence among other chorion genes. It would be particularly interesting to know how extensive a chromosomal region limited to a single developmental period is, and whether it contains copies of more than two different genes.

This work was supported by grants from the NSF and NIH to F.C.K. C.W.J. was supported by an NSF predoctoral fellowship. Clone pc292 was characterised by Dr J. C. Regier and sequenced by Dr S. G. Tsitilou. Initial screening of many chromosomal clones with total chorion cDNA was done by Dr

G. K. Sim. We thank Drs T. Maniatis and W. J. Gehring for helpful discussions.

Recombination of human influenza A viruses in nature

William J. Bean Jr

Division of Virology, St Jude Children's Research Hospital, Memphis, Tennessee 38101

Nancy J. Cox & Alan P. Kendal

WHO Collaboration Center for Influenza, Virology Division, Center for Disease Control, Atlanta, Georgia 30333

In 1977, a unique event occurred in the epidemiology of influenza when a virus of the influenza A (H1N1) subtype, similar to a virus that had occurred in 1950, reappeared and caused worldwide epidemics but did not replace the prevailing influenza A (H3N2) subtype¹⁻⁶. Consequently, the two viruses co-circulated throughout the world^{1,7} and mixed infection of some individuals with both virus strains was detected^{8,9}, raising the possibility that recombination between the two strains might affect the future epidemiological behaviour of influenza. Serological analysis of virus isolates from influenza outbreaks during the winter of 1978-79, however, failed to detect any antigenic hybrids (H3N1 or H1N2). The investigation described here, was therefore, undertaken to detect recombinants among recent isolates of the H1N1 and H3N2 serotypes, involving genes coding for other than the surface proteins by RNA-RNA hybridisation. We report here the genetic characterisation of recombinants of both antigenic types.

Sequence homologies of the genome RNA segments of influenza virus isolates were compared using a competitive RNA-RNA reassociation assay and by direct RNA-RNA hybridisation¹⁰. For the competitive reassociation assay double-stranded RNA probes were prepared by annealing ¹²⁵I-labelled individual RNA segments to homologous unlabelled cRNA. To

determine if a particular virus isolate contains an RNA segment related to that of a labelled reference RNA segment, the double-stranded RNA was melted and allowed to reanneal in the presence of increasing amounts of RNA from the virus isolate being tested. If the unlabelled viral RNA contains an RNA sequence identical to that of the ¹²⁵I-labelled segment, the unlabelled RNA will then compete for annealing sites on the complementary RNA and prevent the reannealing of the labelled RNA. If, however, the unknown virus RNA does not contain an homologous segment or contains one that is only partly homologous, then the RNA either would not compete for annealing sites on the cRNA or it would compete less efficiently and the labelled RNA would reanneal completely or partly with the cRNA.

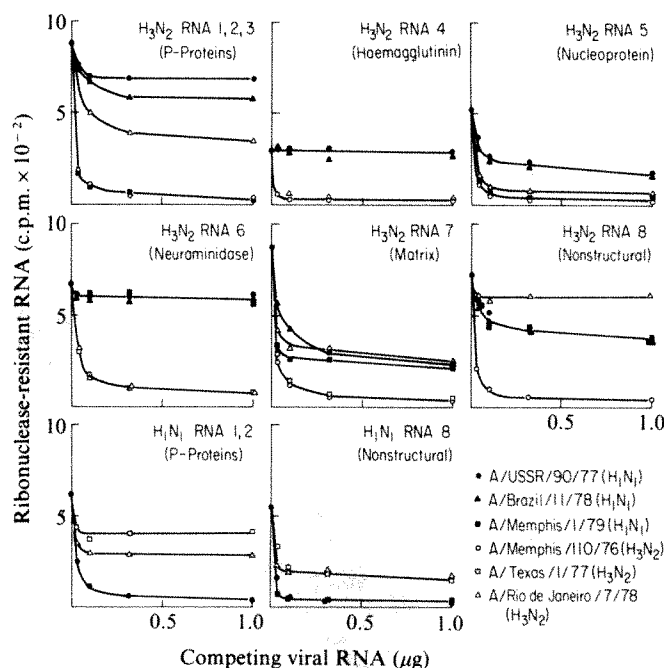

Fig. 1 Comparison of the RNA segments of recent influenza isolates with those of previous H3N2 and H1N1 strains by competitive hybridisation. The growth and purification of virus and the extraction of viral RNA has been described^{16,17}. Virion RNA (10 μg) from an H3N2 strain (A/Memphis/110/76) and an H1N1 strain (A/FW/1/50) was resolved into constituent genome segments by electrophoresis on a polyacrylamide-urea slab gel (22 × 14 × 0.15 cm) in 0.1 × Loenings buffer containing 7 M urea¹⁸, and 3% acrylamide cross-linked with 0.37% bis-acrylalcystamine¹⁹. This cross-linking reagent allows the gel to be solubilised by reduction. Electrophoresis was for 16 h at 25 °C with a constant voltage of 200 V. Following electrophoresis the gel was stained with ethidium bromide (5 μg ml⁻¹) and the RNA bands were visualised with a UV lamp and cut from the gel. The three largest RNA segments were not well resolved and were recovered in either one or two fractions. The gel slices were dissolved in 2 ml 0.05 M EDTA containing 10% 2-mercaptoethanol and 20 μg polyuridylic acid. (The poly-U acts as a carrier RNA during subsequent steps, but does not interfere with iodination¹⁷.) The RNA and acrylamide were precipitated and washed with ethanol, resuspended in 2.5 ml sodium acetate buffer (pH 5.0) and the RNA was electrophoretically separated from the acrylamide in an Iso electrophoretic concentrator cell, operated at 50 V for 2 h. The RNA was recovered in 0.2 ml and ethanol precipitated. Each RNA segment was iodine labelled using 800 μCi ¹²⁵I as described by Commerford²⁰. The iodinated RNA was further purified by cellulose chromatography to remove contaminating ¹²⁵I-labelled material²¹. Complementary RNA was extracted from infected canine kidney cells as described by Etkind and Krug²². Double-stranded (ds) RNA probes were made by annealing each ¹²⁵I-labelled RNA segment to an excess of homologous complementary RNA and then removing remaining single-stranded RNA by digestion with nuclease S1 as described by Hay *et al.*²³. Each competitive reassociation assay used a constant amount of a ¹²⁵I-labelled ds probe and varying amounts of unlabelled RNA extracted from the strains being compared with the reference RNA segments. Reactions were carried out in 15 μl 2.3 × SSC, 50% formamide²⁴. The mixtures were heated at 90 °C for 90 s and then allowed to reanneal at 70 °C for 40 h. Acid precipitable radioactivity was determined by liquid scintillation counting following digestion with ribonuclease A and T₁ (ref. 24).

Table 1 Homology between RNAs of reference influenza virus and isolates, detected by quantitative RNA-RNA hybridisation

Complementary RNA from:	% Homology of cRNA with ³² P-labelled virion RNA segments					
	1	2	3	5	7	8
Reference virus		P		NP	M	NS
A/Texas/1/77(H3N2)	100	100	100	100	100	100
A/USSR/90/77(H1N1)	66	44	54	62	76	78
Recent isolates						
A/Shanghai/9/79(H3N2)	97	(105)		94	99	100
A/Singapore/333/79(H3N2)	110	(102)		98	101	97
A/Brazil/11/78(H1N1)	59	27	53	55	82	77
A/California/10/78(H1N1)	93	103	107	74*	84	73
A/Texas/8/78(H1N1)	92	97	98	79*	74	75
A/Texas/10/78(H1N1)	100	91	108	74*	78	80

Quantitative RNA-RNA hybridisations were carried out by annealing individual ³²P-labelled virion RNA segments from A/Texas/1/77 with homologous or heterologous complementary RNA as described by Scholtissek *et al.*¹⁰. ³²P-labelled virion RNA from the two reference influenza strains was extracted from virus grown in chick embryo kidney cells in the presence of ³²P and the individual genome RNA segments were isolated following polyacrylamide gel electrophoresis as described previously¹⁴. Complementary RNA was isolated from infected, cycloheximide-treated, chick embryo fibroblast cultures using the method of Stephenson *et al.*¹⁵. The labelled RNA segments were annealed to an excess of homologous or heterologous complementary RNA in 2×SSC and then heated at 75 °C in 1×SSC, 1% formaldehyde before digestion with ribonuclease¹⁰. Values are expressed as per cent of counts protected in the homologous reaction. Genes 4 and 6 were not analysed by hybridisation because they could be readily identified by antigenic analysis. Values greater than 100% reflect the error inherent in measurements of this type. The standard error of the procedure determined by repetitive tests of different RNA segments is ±5%.

* Value <100% probably due to cross-contamination of NP RNA (segment 5) with RNA of N2 neuraminidase (segment 6).

Initial RNA comparisons were made using probes prepared with RNA segments isolated from an H3N2 virus of the Victoria serotype (A/Memphis/110/76) and an H1N1 strain, A/FW/1/50, previously shown to be nearly identical to the 'USSR' virus³⁻⁵. Figure 1 shows results of competitive reassociation assays of various virus strains with the H3N2 probes and two representatives of the H1N1 probes. RNA extracted from the homologous strain or closely related strains gave essentially complete competition of the labelled probes. The heterologous RNAs competed to varying degrees with the different RNA segments. There was, for example, little cross-competition with the genes coding for the surface proteins of the prototype strains (genes 4 and 6), while genes 5 and 7 (nucleoprotein and matrix) showed much more cross-competition, indicating a greater conservation of the base sequence coding for these internal proteins, in agreement with the earlier findings of Scholtissek *et al.*⁴. In all cases, however, competition with RNA derived from the heterologous prototype strain was clearly distinguishable from the homologous competition.

One strain shown in Fig. 1, A/Memphis/1/79 (a recent H1N1 isolate), is clearly a recombinant, as four genes (1, 2, 3 and 5) coding for the three 90,000-molecular weight 'P' polypeptides and for the nucleoprotein are homologous with those of the H3N2 strain, while those coding for the surface proteins and genes 7 and 8, coding for the matrix and non-structural proteins, are homologous with those of the H1N1 strain. Comparable results (Table 1) were obtained by directly hybridising ³²P-labelled gene segments isolated from A/Texas/1/77 (H3N2) with complementary RNA isolated from cells infected with A/California/10/78 (H1N1) and other isolates from early outbreaks of influenza during the winter of 1978-79 in the US (A/Texas/8/78 and A/Texas/10/78). Three other H1N1 isolates obtained during the winter of 1978-79 (A/California/10/78; A/Berkeley/40/78; A/Georgia/64/78) were also tested by competitive hybridisation and shown to be identical recombinants (Table 2).

Many of the recent H1N1 strains mentioned above, which were shown to be recombinants between previous H1N1 and H3N2 viruses, are antigenically indistinguishable when tested with ferret sera or monoclonal antibodies (unpublished data) from A/Brazil/11/78, the prototype for a minor variant of the USSR strain predominant in South America during 1978 (ref.

11). Analysis of the RNAs of this prototype variant (Fig. 1, Table 1) indicated, however, that all of its gene segments were derived from an H1N1 strain.

To determine if the recent circulation of recombinant influenza viruses was limited to the above described H1N1 strains, the genetic composition of some recent H3N2 isolates¹² was also analysed. No evidence was found for the presence of genes of H1N1 origin in H3N2 strains isolated in south-east Asia in 1979 (Table 1). A South American H3N2 virus isolate (A/Rio de Janeiro/7/78), however, proved to have a different genetic composition. When RNA from this strain was tested in competitive reassociation assays (Fig. 1), only genes 4 and 6, coding for the surface proteins, of the H3N2 strain were shown to have homologous counterparts in this virus. The RNA did not contain sequences homologous to the other genes of either the H1N1 or H3N2 prototypes, although gene 5 (nucleoprotein) seemed to be more closely related to the corresponding H3N2 gene than to that of H1N1.

In an effort to determine the origin of the genes coding for the non-surface proteins of this virus, ¹²⁵I-labelled probes were prepared from its RNA segments and these were used in competitive reassociation assays with RNA from a series of 20 viruses. These included representatives of the major human influenza A viruses and selected strains from lower animals, as well as an influenza B virus. Mixtures of H3N2 and H1N1 RNA were also tested to rule out the possibility that this virus might actually be a mixture with two copies of each gene. With each segment only RNA from A/Rio de Janeiro/778 was effective in competition assays. None of the other strains tested were found to contain completely homologous RNA.

Our findings that the H1N1 virus prevalent in the US during the winter of 1978-79 contained four genes from an H3N2 virus, are similar to those of Young and Palese¹³, who studied these viruses by oligonucleotide and peptide mapping. Evidently, this recombinant had a distinct selective advantage over the parental strains. Possibly, the immune status of the population favoured the surface proteins of the H1N1 variant, while the replication complex of the H3N2 strain was better adapted for infection and transmission. The earliest examples of these recombinant viruses so far obtained were isolated in November and December of 1978 (Table 2). As these viruses

H1, RNA segment homologous with corresponding gene of A/USSR/90/77 (H1N1).

H3, RNA segment homologous with corresponding gene of recent H3N2 isolates of the Victoria or Texas serotypes.

?, RNA segment not closely related to H1N1 or H3N2 strains or any other influenza strain yet tested.

are antigenically identical to the H1N1 variant, which was isolated about 6 months earlier, our finding that A/Brazil/11/78 contained all the genes from the USSR strain indicates that the drift of the H1 haemagglutinin from A/USSR/80/77 to A/Brazil/11/78 has occurred independently of recombination.

The significance of the finding that the H3N2 virus A/Rio de Janeiro/7/78, which contains genes coding for surface proteins identical to those of other recent H3N2 isolates, but derives all other genes from an unknown source remains uncertain. This isolate was chosen for study primarily because it came from an outbreak in the same country and in the same week as A/Brazil/11/78, and therefore was of interest to us as a potential recombinant with H1N1 genes. This virus and others from the outbreak also have the unusual property of cross-reacting equally with both the Texas and Victoria serotypes, as recently found for a small number of other H3N2 isolates⁷. It was isolated in chicken embryos and egg passaged several times before use in this study. Neither the hybridisation results nor subsequent cloning have given any evidence that it is a mixture of viruses. The unknown genes of A/Rio de Janeiro/7/78 may have been derived from a previously unrecognised human influenza virus or from some animal influenza that was not tested

in the experiments described here. In either case, the identity of only the haemagglutinin and neuraminidase genes of A/Rio de Janeiro/7/78 with those of recent H3N2 strains suggests that this unusual virus may be a further example of a recombinant virus infecting man.

We thank Mr Raymond Wilson for technical assistance and Dr Peter Palese for prepublication information. This work was supported, in part, by grant AI 14293 from the National Institute of Allergy and Infectious Disease, by Cancer Center Support (CORE) grant CA 21765 from the National Cancer Institute and by ALSAC.

Note added in proof: The unusual H3N2 virus strain described above (A/Rio de Janeiro/78) has recently been analysed by J. Young and P. Palese and shown to be genetically identical to a laboratory-derived recombinant of a Victoria strain in the A/PR/8/34 strain (personal communication). This suggests that A/Rio de Janeiro/78 may not be a natural "recombinant". We cannot be certain, however, whether the isolation of this virus and several other identical isolates was due to actual infection with a laboratory-derived strain or to laboratory contamination of clinical samples. Epidemiological studies to resolve this question are underway.

***E. coli* RNA polymerase promoters on superhelical SV40 DNA are highly selective targets for chemical modification**

Patricia Hale, Richard S. Woodward & Jacob Lebowitz

Department of Microbiology and Comprehensive Cancer Center, University of Alabama in Birmingham, Birmingham, Alabama 35294

Supercoiled DNAs are required or preferred in a number of biological processes such as repair and transcription. This requirement may be due to special properties which are present in supercoiled (FI) DNAs but not in the corresponding allomorphic forms. If sufficiently supercoiled, FI DNAs seem to contain single-stranded regions that are accessible to single-strand specific reagents and endonuclease¹⁻³. The free energy associated with superhelix formation may also be used to drive ligand-DNA or protein-DNA interactions³⁻⁷. *In vitro* studies have shown that superhelical DNA is a better template for transcription than its corresponding allomorphic forms⁸⁻¹⁵, and this is due probably to a change in the initial binding affinity of the RNA polymerase at promotor sites¹⁵⁻¹⁸. Previous work in our laboratory has suggested that the single-strand specific probe *N*-cyclohexyl-*N'*-β-(4-methylmorpholinium) ethyl carbodiimide (CMC), which almost totally inhibits transcription of SV40 and PM2 DNA^{14,18}, is acting preferentially at promotor sites¹⁸⁻²⁰. We report here experiments to determine the selectivity of CMC for promoters on superhelical SV40 DNA. After limited reaction with CMC there was substantially less *Escheri-*

chia coli RNA polymerase bound to reacted SV40 DNA than to the unmodified DNA. Marked inhibition of transcription from the modified DNA demonstrated that CMC is highly selective for *E. coli* RNA polymerase promoters in superhelical DNA, suggesting that the introduction of superhelical turns may alter the parameters by which the enzyme interacts with DNA through promotor recognition and opening of the DNA.

E. coli RNA polymerase was bound to supercoiled SV40 DNA at concentrations exceeding those for saturation as determined by previous experiments¹⁵. Complexes were cross-linked, purified and cleaved with *Hpa*II (Fig. 1). *Hpa*II endonuclease cleaves SV40 at 0.735 map units; this area does not contain any *E. coli* RNA polymerase binding sites¹⁵. Typical SV40 DNA complexes with *E. coli* RNA polymerase are shown in Fig. 1. This figure also demonstrates the efficient removal of excess polymerase and glutaraldehyde by Sepharose 6B column chromatography (full details will be published elsewhere). *E. coli* RNA polymerase binding sites were precisely mapped on over 400 DNA-RNA polymerase complexes in three separate experiments. Figure 2 gives map measurements of ~200 molecules in one experiment. *E. coli* RNA polymerase binding sites were consistently observed at positions 0.13, 0.18-0.21, 0.47, 0.52-0.53, 0.60-0.62, 0.65, 0.82, 0.925 and 0.975 map units on an SV40 map using the single *Eco*RI cleavage site as map position 0.0. As the number of bound polymerase molecules increased, it became more difficult to spread the DNA sufficiently for this type of map measurement. Most complexes containing nine molecules of RNA polymerase per DNA molecule were observed in a collapsed form due to polymerase-polymerase interactions. Therefore, most molecules used in map measurements contained five or six polymerase per DNA molecule. However, the localisation of binding sites on a subpopulation of molecules that contained nine molecules per

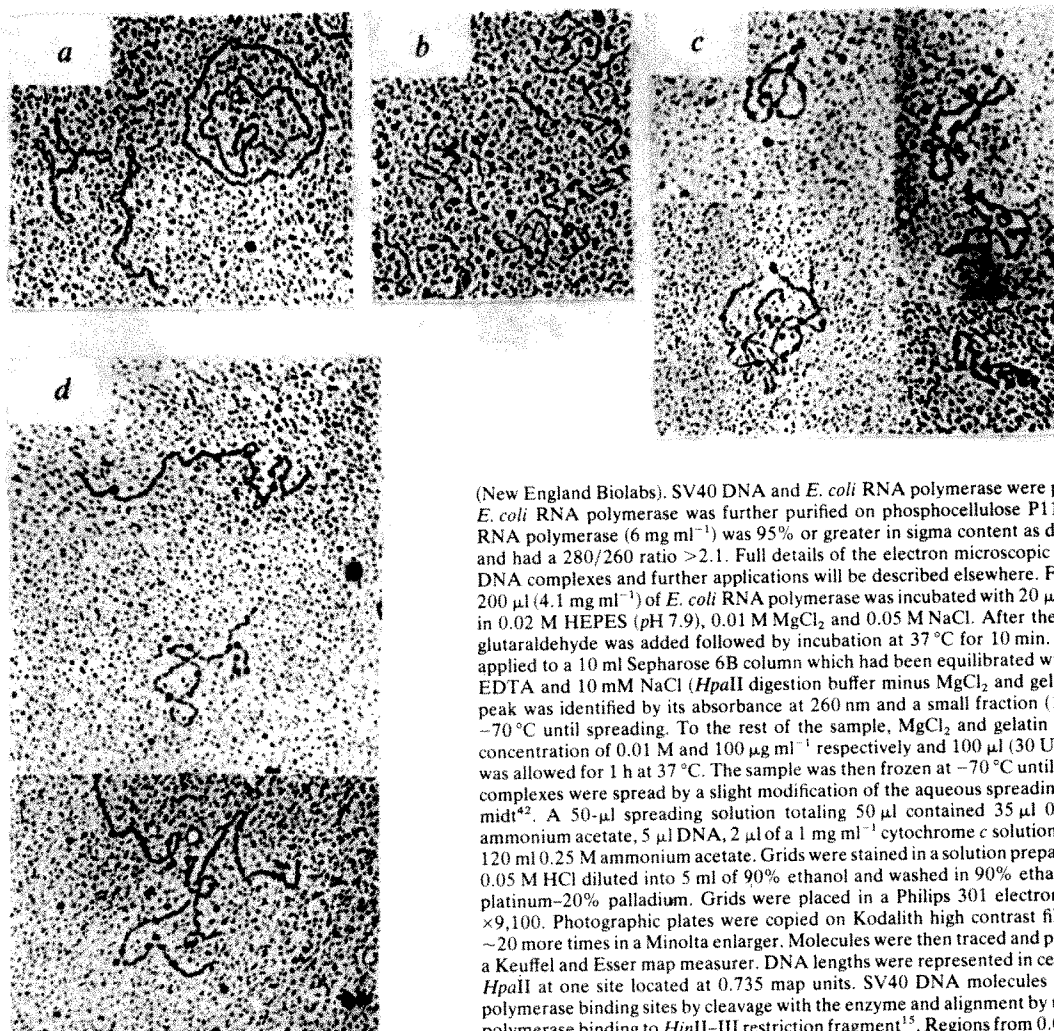

Fig. 1 Enhanced visualisation of glutaraldehyde-fixed RNA polymerase-SV40 DNA complexes by removal of excess RNA polymerase and fixative using Sepharose 6B column chromatography. (New England Biolabs). SV40 DNA and *E. coli* RNA polymerase were prepared as described previously¹⁵. *E. coli* RNA polymerase was further purified on phosphocellulose P11 as described previously⁴⁰. *E. coli* RNA polymerase (6 mg ml⁻¹) was 95% or greater in sigma content as determined by rifampin inhibition⁴¹ and had a 280/260 ratio >2.1. Full details of the electron microscopic visualisation of RNA polymerase-DNA complexes and further applications will be described elsewhere. For binding of polymerase to DNA, 200 μ l (4.1 mg ml⁻¹) of *E. coli* RNA polymerase was incubated with 20 μ g of SV40 DNA at 37 °C for 30 min in 0.02 M HEPES (pH 7.9), 0.01 M MgCl₂ and 0.05 M NaCl. After the 30 min incubation, 6.25 μ l of 8% glutaraldehyde was added followed by incubation at 37 °C for 10 min. The sample was then immediately applied to a 10 ml Sepharose 6B column which had been equilibrated with 10 mM HEPES (pH 7.4), 1 mM EDTA and 10 mM NaCl (*HpaII* digestion buffer minus MgCl₂ and gelatin). The DNA-RNA polymerase peak was identified by its absorbance at 260 nm and a small fraction (100 μ l) was removed and frozen at -70 °C until spreading. To the rest of the sample, MgCl₂ and gelatin (autoclaved) were added to a final concentration of 0.01 M and 100 μ g ml⁻¹ respectively and 100 μ l (30 U) of *HpaII* was added and digestion was allowed for 1 h at 37 °C. The sample was then frozen at -70 °C until DNA and DNA-RNA polymerase complexes were spread by a slight modification of the aqueous spreading technique described by Kleinschmidt⁴². A 50- μ l spreading solution totaling 50 μ l contained 35 μ l 0.001 M EDTA (pH 7.5), 5 μ l 5 M ammonium acetate, 5 μ l DNA, 2 μ l of a 1 mg ml⁻¹ cytochrome *c* solution. The hypophase solution contained 120 ml 0.25 M ammonium acetate. Grids were stained in a solution prepared with 5 μ l 0.05 M uranyl acetate, 0.05 M HCl diluted into 5 ml of 90% ethanol and washed in 90% ethanol, dried and shadowed with 80% platinum-20% palladium. Grids were placed in a Philips 301 electron microscope and photographed at $\times 9,100$. Photographic plates were copied on Kodalith high contrast film (Eastman-Kodak) and enlarged ~ 20 more times in a Minolta enlarger. Molecules were then traced and polymerase positions measured using a Keuffel and Esser map measurer. DNA lengths were represented in centimetres. SV40 DNA is cleaved by *HpaII* at one site located at 0.735 map units. SV40 DNA molecules could be orientated for location of polymerase binding sites by cleavage with the enzyme and alignment by using the information obtained from polymerase binding to *HinII*-III restriction fragment¹⁵. Regions from 0.05 to 0.01, 0.03 to 0.04, 0.65 to 0.75

and 0.93 to 0.965 map units did not contain polymerase binding sites¹⁵. This allowed only one possible orientation for essentially all of the molecules that were measured. The number of polymerase molecules bound to each DNA molecule was counted directly from the photographic plates. Before spreading, relaxed circular SV40 DNA was added to DNA-RNA polymerase complexes in a concentration of 0.5 μ g ml⁻¹. This DNA acted as a marker for determining full-length DNA-RNA polymerase complexes for mapping of polymerase binding sites. At this concentration, at least 4 or 5 measurable circular molecules of SV40 DNA were found on each photographic plate.

DNA molecule and were sufficiently spread for map measurement gave a similar result (data not shown).

The total number of *E. coli* RNA polymerase molecules bound to each SV40 FI DNA molecule was determined for over 400 complexes at saturating concentrations of *E. coli* RNA polymerase (see Fig. 3a for data on molecules used for map measurements in Fig. 2). A maximum was observed at nine polymerase molecules per DNA molecule. The results indicate that in the supercoiled form of SV40 DNA there are nine specific RNA polymerase binding sites which may be occupied at saturating concentrations of the enzyme. No preferential binding to any particular site was observed, although increased stability from dissociation has been observed for the binding sites at 0.13 and 0.18-0.21 map units (P. Hale, unpublished observation).

The apparent equilibrium reactivity of the single-strand regions in the superhelical form is between 108 and 121 CMC molecules in the conditions used^{19,21}. No detectable reaction of nicked SV40 DNA was observed and saturating ethidium bromide density measurements did not detect any significant decrease in superhelical density²¹.

We have studied polymerase binding to, and template activity of, SV40 FI DNA which has been modified by 7 and 15 min of CMC reaction. The mean extent of carbodiimide binding after 15 min of reaction is 10.7 molecules CMC per molecule SV40 as determined by buoyant density analysis²² (Fig. 4). The linear nature of the kinetics allows interpolation to 7 min of reaction;

after fitting the data to a straight line, the mean reactivity at 7 min was found to be 5.0 CMC molecules per SV40 DNA molecule.

Evaluation of the extent of RNA polymerase binding by electron microscopy as well as the inhibition of transcription in

Fig. 2 Map location of *E. coli* RNA polymerase binding sites on native SV40 DNA FI as determined by electron microscopy. Samples were prepared as described in Fig. 1.

Table 1 Comparison of RNA polymerase binding and transcription between untreated SV40 FI DNA and 7 and 15 min CMC-reacted DNA

A	B	C	D	E	F	G
CMC reaction (min)	Moles CMC per mole DNA	Mean moles polymerase per mole DNA	Moles CMC per polymerase binding site	% Inhibition of polymerase binding	% Inhibition of transcription -Rif	% Inhibition of transcription +Rif
0	0	7.1	0	0	0	0
7	5.0	—	0.56	—	35%	54%
15	10.7	4.5	1.2	37%	61%	88%

A, SV40 DNA I (25 μ g) was reacted with a 500 molar excess of CMC and purified from excess reagent as previously described¹⁸. B, The molecules of CMC bound per molecule of SV40 DNA were determined by buoyant density analysis as shown in Fig. 4. The 7-min reaction was interpolated from the data. C, The mean number of RNA polymerase molecules per SV40 DNA was determined from the data in Fig. 3. D, The number of CMC molecules per RNA polymerase site was calculated by dividing column B by nine, the total number of RNA polymerase binding sites on untreated SV40 DNA. E, The per cent inhibition of binding was calculated from the data of column C. F and G represent transcription assays of RNA polymerase-SV40 DNA complexes before preparation for electron microscopy. Transcription assays were performed as previously described^{15,18}, with DNA and polymerase incubated together for 10 min before the addition of nucleotide triphosphates (NTP). In transcription assays containing CMC-reacted DNA, DNA was incubated in transcription buffer 10 min before polymerase addition as previously described¹⁸. CMC reactions were repeated 4 times with per cent inhibition of transcription, with or without rifampin, showing reproducibility of $\pm 2\%$. Rifampin, 4 μ g ml⁻¹, was added with NTP in column G.

the presence and absence of rifampin should reveal whether extremely limited CMC modification is specific for promoter sites. The electron microscopy technique described was used to study the effects of 15-min CMC modification of the DNA on RNA polymerase binding (Fig. 3b). Maximum binding of RNA polymerase was observed at five polymerase molecules per DNA molecule. This loss of RNA polymerase binding is compared with the inhibition of transcription in Table 1. It can be seen that an average of 1.2 CMC molecules per polymerase site is sufficient to produce a 37% loss of binding as judged by electron microscopy (Table 1, D, E). Transcription inhibition of 61 and 88% occurred in the absence and presence of rifampin respectively (Table 1, F, G). Although electron microscopic mapping was not carried out on the 7 min CMC-reacted DNA (5.0 CMC per SV40 DNA) the lower inhibition of transcription is consistent with the data obtained for the 15-min CMC-reacted DNA (10.7 CMC per SV40 DNA). These results show that the *E. coli* RNA polymerase promoters on SV40 DNA FI exist in a state, or states, readily accessible to extremely limited modification by a reagent highly selective for unpaired bases. Rifampin resistance measures the capacity to initiate rapidly a ternary complex for transcription. Previous work with native SV40 DNA has shown that there is essentially no difference in transcription with or without rifampin¹⁵. Here we observe that on very limited CMC modification rifampin causes a further decrease in transcription of about 20% (Table 1, F, G) compared with transcription without rifampin. Hence it seems that CMC modification enhances rifampin sensitivity by weakening promoters. This is supported by earlier data for 2-h (CMC-reacted) SV40 DNA tested for rifampin sensitivity. In these experiments, sensitivity to the drug was measured by differences in template saturation at different rifampin concentrations¹⁸. The saturation point was decreased by 26 and 47% for 2 and 4 μ g ml⁻¹ rifampin, respectively. Unmodified SV40 DNA FI is insensitive to increase in rifampin from 2 to 8 μ g ml⁻¹ (ref. 15). The capacity of CMC to weaken or block RNA polymerase binding could depend on the nature of individual promoters. This has been tested by mapping the binding sites for one of the modified SV40 DNA samples.

Figure 5 shows the results of mapping RNA polymerase molecules bound to 15 min CMC-reacted SV40 FI DNA. When these results are compared with those for the untreated DNA (Fig. 2), it can be seen that the location of the sites is very similar on both the CMC-reacted and unmodified DNA. Nine sites are observed at map positions 0.11, 0.18–0.19, 0.46, 0.54, 0.60, 0.63, 0.83, 0.925 and 0.98. The binding sites were observed to be more heterogeneous on the CMC-reacted DNA, this may be due to the decrease in rifampin-resistant tight binding sites on the CMC-modified DNA. This would be anticipated if CMC modification in or near a given promoter could occur at different locations leading to a variation in binding position around the promoter site. No specific population of sites was observed to be particularly sensitive to CMC reaction or preferentially lost by a 15-min reaction of the DNA with CMC.

Also note that CMC modification increases RNA polymerase binding around the 0.30 and 0.40 map positions to a small extent. Recent assays of unmodified SV40 DNA restriction fragments retained on nitrocellulose filters by RNA polymerase show that these regions do contain weak affinity for the enzyme (P.T. Chan, unpublished observation).

The use of a slow-reacting reagent^{19,21} (108–124 molecules CMC/SV40) and only short reaction times has allowed us to limit the reaction to approximately one CMC per promoter. This situation precludes propagation of denaturation into RNA polymerase binding regions by modification at neighbouring sites. No significant loss of superhelical turns can occur with only

Fig. 3 The respective distributions of the number of *E. coli* RNA polymerase molecules per SV40 FI DNA for: a, unmodified; and b, 15 min. CMC-modified DNA. Supercoiled SV40 FI native or CMC-modified DNA was incubated with *E. coli* RNA polymerase, cross-linked with glutaraldehyde, chromatographed on Sepharose 6B and cleaved with *Hpa*II as described in Fig. 1. The resulting complexes were then spread for electron microscopy as described. The number of RNA polymerase molecules per DNA molecule were counted directly from the photographic plates. The reaction of SV40 FI DNA with CMC was performed at a 500-fold molar excess of CMC to nucleotides for 15 min at 37°C and excess reagent was removed by chromatography on BioGel A5m as described previously¹⁸. CMC-modified DNA was incubated with bovine serum albumin (0.5 mg ml⁻¹) for 10 min at 37°C before polymerase addition to absorb residual CMC¹⁸.

Fig. 4 Extent of CMC modification of SV40 DNA I as a function of time. The amount of CMC bound in the conditions described in Fig. 3 was evaluated using the equation of Bauer and Vinograd²²

$$\nu' = \frac{\theta(\bar{\nu}_3 + \Gamma') - (1 + \Gamma')}{(1 - \bar{\nu}_4\theta)}$$

where ν' is g of reagent bound per g of DNA; θ , the buoyant density of the modified DNA; $\bar{\nu}_3$, the partial specific volume of anhydrous DNA (0.479); Γ' , the net hydration of the modified DNA; and $\bar{\nu}_4$ the partial specific volume of CMC (0.814). Γ' was evaluated by the equations developed by Bauer and Vinograd²². The moles of CMC per mol of nucleotide was obtained by multiplying ν' by 430/423, the respective molecular weights of a Cs nucleotide and CMC. The buoyant density of SV40 DNA was determined from a G-C content of 0.4067 from the full sequence data²⁸ using the relationship $\theta = 0.0988 (G-C) + 1.6541$. This gives a θ value for SV40 DNA of 1.6944 g cm^{-3} . The above unpublished equation for θ against (G-C) is relative to a θ value for *E. coli* DNA of 1.7035 g cm^{-3} (ref. 43) and simply modifies the intercept of previous equations⁴⁴. Analysis of buoyant density was carried out by the method of Vinograd and Hearst⁴⁴ using *Micrococcus lysodeikticus* DNA as a marker. The θ value for the latter was found to be 1.7271 g cm^{-3} relative to SV40 DNA. Buoyant densities were determined in a Beckman model E analytical ultracentrifuge. All experiments were carried out at 40,000 r.p.m. and 20°C using a solvent consisting of 10 mM Tris, 1 mM Na_3EDTA (pH 8.0) and the appropriate amount of CsCl (Metallgesellschaft). Cells were scanned in conditions which yielded a magnification factor of ~ 19 . The chart recording was measured with a precision ruler (Keuffel and Esser). The total uncertainty in the measurement of the marker and sample peaks on the scanner trace was $\pm 0.04 \text{ cm}$, corresponding to an experimental precision of θ of $\pm 0.0003 \text{ g cm}^{-3}$, equivalent to ± 5.4 CMC molecules per molecule of DNA. The determination of θ is the major source of experimental error as transcription studies have shown that there is no greater than 2% difference between identical repeat reactions.

11 CMC molecules per SV40 DNA, thus excluding the possibility that CMC modification removes sufficient superhelical turns to reduce the torsional forces that may be responsible for structural alterations in promoters. Several models could explain why *E. coli* RNA polymerase binding sites are highly selective targets for CMC modification: (1) Supercoiling produces open promoters of single-strand character, allowing enhanced binding of RNA polymerase. This would explain the extreme sensitivity of promoters to CMC modification, as reactivity occurs at the imino sites of thymine and guanine and requires unpaired bases; (2) The promoter regions are made highly reactive due to structural transitions that are not presently understood; (3) CMC reactivity that occurs by either of the above models may be localised at sites adjacent to the promoter and perturb structural transitions that a promoter must undergo for appropriate recognition by RNA polymerase. This action at a distance or telestability²³ may be due to the CMC-induced disruption of "barriers, sinks or sources of sequence-specific conformational preference"²⁴ that may be needed to produce the recognition site for RNA polymerase.

Support for the localisation of altered secondary structure comes from a very recent study of Shishido²⁵ using S_1 endonuclease to map preferential unpaired or weak duplex regions in SV40. The cleavage sites were found at 0.15, 0.28, 0.38, 0.39, 0.44, 0.56, 0.89 and 0.98 SV40 map units. The average distance of an RNA polymerase molecule from a respective S_1 site is 0.032 map units (167 base pairs). Given an

uncertainty of ± 0.02 map units (103 base pairs) for the assignment of RNA polymerase binding sites by electron microscopy leads us to conclude that six of the S_1 sites are in close proximity to RNA polymerase binding regions.

If a promoter constitutes approximately 60 base pairs²⁶ one would anticipate that CMC modification would produce a differential effect on binding dependent on its location, that is directly in the promoter sequence or at adjacent sites upstream or downstream. This would eliminate binding in some cases but only weaken binding in others. However, if initiation is dependent on a precise RNA polymerase-DNA interaction one would anticipate a more drastic effect on transcription. This seems to be the case (Table 1) and is supported by our previous observation that rifampin sensitivity ($2-8 \mu\text{g ml}^{-1}$) is not seen until SV40 FI DNA is modified with CMC¹⁸. Hence one CMC per promoter produces a 37% loss of binding which represents an 88% decrease in transcription in the presence of $4 \mu\text{g ml}^{-1}$ rifampin.

All the RNA polymerase sites appear to be equally sensitive (Fig. 5) towards initial CMC modification. However, it has been shown that if CMC reactivity is allowed to continue for 24 h the reagent is redistributed as follows¹⁹: 80 CMC molecules mapping between 0.65 and 0.43 map units; 31 CMC molecules mapping between 0.32 and 0.17 map units; 10 CMC molecules mapping between 0.17 and 0.10 map units. This data is based on a low specific activity ^{14}C -CMC probe available at that time that would not detect less than 5 CMC molecules per restriction fragment.

Thus it seems that supercoiling has the capacity to generate well separated localised sites. However, further chemically induced melting seems to coalesce open regions as a function of A-T content²⁷. Although the molecular details need to be resolved for a full understanding of the structural features of DNA that may be varied and generated by supercoiling, it is striking that altered or open secondary structure can be generated at highly preferential sites. This has considerable implications for biological recognition and the modulation of gene expression. Additional evidence supporting the role of supercoiling in transcription has been recently obtained for promoters in plasmids²⁸. Also, some promoters located in linear DNA are sensitive to novobiocin which inhibits DNA gyrase²⁸.

The study of SV40 DNA provides a useful model for the comparative analyses of *in vivo* and *in vitro* functional regions of DNA with regard to the expression and regulation of gene products. SV40 FI DNA can be transcribed by *E. coli* RNA polymerase and the resulting cRNA produces T antigen immunoprecipitated products in a variety of *in vitro* translation systems²⁹⁻³². In addition, linked transcription-translation systems have yielded the major capsid protein VP1, using *E. coli* RNA polymerase³¹⁻³⁴.

Figure 6 is a map of the early and late regions of SV40 DNA showing the sites of *E. coli* RNA polymerase binding. Figure 6a shows that *E. coli* RNA polymerase can initiate at six sites from the early region. These correspond quite well with the mapping

Fig. 5 Map location of *E. coli* RNA polymerase binding sites on 15 min CMC-modified SV40 FI DNA as determined by electron microscopy. Samples were prepared as described in Fig. 1.

Fig. 6 Location of the *E. coli* RNA polymerase molecules in the early (a) and late (b) regions of SV40 DNA. The respective regions of the SV40 DNA map are expressed in a linear form with relative lengths measured from the *EcoRI* position assigned 1.0 or 0.0. In both cases mRNA synthesis is expressed from left to right, 5' to 3'. The origin of replication is indicated by O_R and the cytoplasmic mRNAs are shown by dashed lines. a, The early region contains an intron sequence and two splices occur which are indicated by the large and small $V^{33,45,46}$. The two mRNAs that are produced consist of 0.65 to 0.55 and 0.65 to 0.60 fused respectively to the main body of the message 0.54 to 0.17. The larger mRNA, that is with the smaller spliced out regions, retains the UAA stop codon³³ shown at 0.547 and hence protein synthesis only produced a 17,000 molecular weight (MW) protein, little t antigen. The small mRNA, with the entire intron sequence spliced out produces large T antigen, with an approximate MW of 80,000. The UAA stop codon for this protein is shown at 0.175. b, The late region of SV40 coding for viral proteins VP1, VP2, and VP3. (ref. 33). The lower dashed line represents the 19S mRNA coding for VP2 and VP3 with AUG initiation codons at 0.767 and 0.835, respectively.^{33,34}. These overlapping proteins are terminated by the stop codon UAA shown at 0.969 (ref. 33). The upper dashed line represents 16S mRNA coding for VP1 with initiation of protein synthesis from the AUG codon shown at 0.947 and termination at the UGA codon shown at 0.155 (refs 33, 34). The reading frame for VP1 (16S mRNA) is different than VP2 or VP3 (19S mRNA) and the UAA stop at 0.969 is not recognised³³. The respective AUG initiation and UAA or UGA termination codons have been determined from DNA and protein sequence data³³. No attempt has been made to show the variable 5' leader splicing that occurs from the region 0.721 to 0.760 which is attached to late 19S and 16S mRNAs³⁴. These may be involved in the control of the expression of VP2 and VP3.

of [γ -³²P] ATP initiations at 0.17, 0.45, 0.52, 0.61 and 0.65. The promoter at 0.65 would generate cRNA with translation stop signals³³, hence only the region from 0.65 to 0.55 can be translated. This would produce small t antigen. The promoters at 0.53 and 0.47 would produce cRNAs that could be translated into T antigen-like proteins. The two promoters between 0.20 and 0.10 should not produce any significant T antigen-like proteins. Figure 6b compares the *E. coli* RNA polymerase binding sites of the late region to *in vivo* functions. We observe that the enzyme binds before the appropriate initiation codons that would produce VP3 and VP1. The latter is the major capsid protein whereas VP2 and VP3 represent minor structural proteins^{24,33}.

It is striking that *E. coli* RNA polymerase recognises regions in the correct polarity proceeding AUG initiation codons for two out of three late gene products as well as the AUG initiation codon for T antigens. The other binding sites for the enzyme, except the 0.13 site, all occur before open reading frames with potential codons for initiation. With regard to primary sequence recognition sites, it has already been established that there is a promoter sequence for tight binding of *E. coli* RNA polymerase at 0.165 on the SV40 DNA map³⁵. Examination of the remaining SV40 DNA sequence (ref. 33 and P. T. Chan, unpublished data) reveals promoter sequences³⁶ that could fit with our electron microscopy RNA polymerase binding analysis with the exception of the 0.65 site. However, this site is very A-T rich³³ and may be easily opened to serve as a promoter. Many other potential promoter sequences are also available but not used, suggesting that some of the *E. coli* RNA polymerase recognition sites that are used share similar features with the eukaryotic RNA polymerase II. This is supported by a correspondence of five of six binding sites for the respective enzymes on polyoma DNA using electron microscopy mapping^{37,38}. A recent report indicates that *E. coli* RNA polymerase binds to the appropriate sites on adenovirus DNA for the production of some of the late mRNAs³⁹.

The evidence that supercoiling has a significant role in the modulation of gene expression in prokaryotic systems is quite compelling. The possibility that modulation of supercoiling occurs through the changes in binding of histone and non-histone proteins would be a plausible extension of these results. The finding that superhelical turns makes promoters highly preferential targets for carbodiimide modification opens new possibilities for exploring the structural transitions produced in DNA by the torsional stress of supercoiling.

We thank John Fitzpatrick for technical assistance, Peter Chan for discussions and Carolyn Harris for preparation of the

manuscript. This work was supported by grants CA17077 from the NCI and PCM 7808589 from the NSF. Patricia Hale was supported by National Research Service Award T32CA09128 from the NCI.

DRUGS AND IMMUNE RESPONSIVENESS – A Biological Council Drug Action Symposium Edited by J. L. Turk and Darien Parker

J. L. Turk is Sir William Collins Professor of Pathology at the Institute of Basic Medical Sciences, University of London, and the Royal College of Surgeons.

Dr Darien Parker is a member of the Department of Pathology at the Royal College of Surgeons.

1979; £12.95; 256pp; 0 333 26425 8

CONTENTS

Immunosuppressive effects of miscellaneous agents-G.L.Floersheim; Drug specificity in the suppression of the immune response-E.Mihich; The effects of PAM and other thiols on lymphoid cells-G. Harris; The effect of penicillamine on humoral and cellular immune responses in animals-I. Hunneyball; Approaches to prevention and treatment of drug allergy-A. L. de Weck; Principles, technical difficulties and developments of radioimmunoassay procedures- L. Wide; Enzymoimmunoassays and related analytical techniques for drugs-J. Landon; New approaches to linkage of haptens for radioimmunoassay-W. M. Hunter & J. E. T. Corrie; Effect of drugs on immunological control mechanisms-J. L. Turk; Immunological profile of levamisole, a possible thymoninetic agent-J. De Cree; Levamisole and oral inflammation-T. Lehner; New developments in drugs enhancing the immune response-P. Dukor; Drugs as haptens-J. Dewdney; Allergic reactions to high molecular weight compounds-D. R. Stanworth; Tolerance and delayed hypersensitivity-L. Polak; Adverse reactions to Practolol-G. E. Davies.

In this work leading international authorities discuss some of the issues in the field of immunopharmacology concerned with the interactions of drugs and the immune response. The result is a valuable survey of a burgeoning field and will be essential reading for all those already working in immunopharmacology or about to begin doing so.

ENZYME INHIBITORS AS DRUGS – A Biological Council Drug Action Symposium.

Edited by Professor Merton Sandler, Professor of Chemical Pathology at the Bernhard Baron Memorial Research Laboratories.

Spring 1980; £18; 250pp; ISBN 0 333 289846

CONTENTS

Overview: Kinetics and enzyme inhibition studies-K. Tipton; Design of irreversible enzyme inhibitors -E. Shaw; Design of transition state analogues as competitive reversible enzyme inhibitors -G. E. Leinhard; Molecular orbital studies-J. K. Seydel & K. J. Schaper; Design of suicide inactivators for pyridoxal phosphate dependent enzymes-R. A. John; Theory into practice (chemistry and pharmacology of the Merrell range of inhibitors-M. J. Jung, J. Koch-Weser & A. Sjoerdsma; Acetylcholinesterase inhibitors-W. N. Aldridge; Phosphodiesterase inhibitors-Harris, Phillips, Goldenberg & Asaad; Monoamine oxidase inhibitors: Introduction-H. Blaschko; Monoamine oxidase inhibitors: chemistry and pharmacology-J. Knoll; Monoamine oxidase inhibitors in the field -M. Sandler; B-Lactam antibiotics (1)-Sander, Glover, Elsworth, Lewinsohn & Reveley; B-Lactam antibiotics (2)-Frere, Duez, Dusart, Coyette, Leyh-Bouille, Ghuysen, Dideberg & Knox; Inactivation of B lactamase by mechanism based reagents-Fisher & Knowles; Proteinase inhibitors: potential drugs? -A. J. Barrett; Angiotensin-converting enzyme inhibitors-Cushman, Ondetti, Cheung, Sabo; Antonaccio & Rubin; Inhibitors of arachidonic acid metabolism-Moncada & Vane; Dihydrofolate reductases as targets for selective inhibitors-Hitchings & Roth.

This is a new volume in the Biological Council's Drug Action Symposia Series. It covers the developing links between enzymology and pharmacology and the rapidly expanding new field in pharmacology which results from these links. This work will be welcomed as a valuable survey by all those involved in pharmacology, enzymology and immunology and by students taking courses in these studies.

**A highly
topical subject!**

The Interferon System

By **William E. Stewart II, Ph.D.**,
Interferon Laboratories,
Sloan-Kettering Institute for Cancer Research,
New York, N. Y., USA

1979. 23 figures. XII, 421 pages.
Cloth DM 98,-; AS 676,-
ISBN 3-211-81505-8

From the reviews:

"This book is a comprehensive review of the entire interferon literature, and fills a considerable gap.

It is the potential use of interferon as an antitumour agent that has attracted most recent attention, for, stimulated by a careful ongoing trial against osteogenic sarcoma in Sweden, there have been several well-publicised reports of its activity against human cancer in the USA.

The book is therefore timely. Interferon research has continued apace and we greatly need a good critical summary. The book will be invaluable for those who are starting research in the area, but also for those who, like the reviewer, have been in the field a long time. ... The bibliography contains nearly 2500 references.

The author is to be congratulated on a fine achievement, and the book will be greatly used ..."

Cloth Dfl. 38,- / US \$ 19.95 ISBN 90-277-1054-6

'Shrader-Frechette documents with relentless and ruthless efficiency and detail, the dangers of providing power through nuclear energy. Not only do we see the madness of a policy which can lead to Three Mile Island disasters or worse, but we learn of the constant dangers even when things are working well. What makes her work doubly impressive, is that she brings to her study the mind of a trained philosopher, while showing skill and sensitivity in her discussions of methodological issues and ethical questions.' BOOK REVIEWS

Intelligence for beginners?

Donald D. Dorfman

EYSENCK'S new book on intelligence is his first to appear since Leon Kamin reported gross irregularities in Sir Cyril Burt's data. The main purpose of his book is to present "what to the author appears to be the paradigm towards which the research of the past 80 years converges" (page 6). The book is "intended for beginners" (page 6). An author of a work intended for beginners has an obligation to give a balanced and scrupulous description and analysis of the historical and scientific data.

On page one of his book, Eysenck refers the reader — presumably a beginner — to his appendix A which "gives a short account of the facts of the Burt affair". He implies in that appendix that Arthur Jensen was the first to discover anomalies in Burt's data. Leon Kamin — the actual discoverer — is never mentioned in that historical account.

In his first chapter, "Intelligence: The Development of a Concept", Eysenck concludes that culture-bound intelligence tests are admissible for pupil and student selection at school and university because "we are often justified in assuming considerable uniformity in cultural background among candidates" (page 23). Eysenck gives no justification for his cultural-uniformity hypothesis.

His review of the evidence for a correlation between IQ and amplitude and latency of evoked cortical potentials is misleading. The figures that he displays in support of a strong correlation are taken from Ertl's early work which even Eysenck admits "suffered from technical and methodological deficiencies" (page 50). He then asserts that Shucard and Horn have also obtained "quite sizable correlations between AEP's [averaged evoked potentials] and IQ" (page 50). In fact, those investigators reported a correlation of only +0.24 for fluid intelligence and an absence of correlation for crystallized intelligence in the article cited by Eysenck. He also presents data from "our own laboratories" collected in about 1973. No details are given and no reference is made to any relevant publications in scholarly journals.

Eysenck's introductory text is also interspersed with political comments. For instance, in his discussion of IQ and job success, he tells us that "in our type of society there is little evidence of political

The Structure and Measurement of Intelligence. By Hans J. Eysenck. Pp.253. (Springer: Berlin, Heidelberg and New York, 1979.) DM 44, \$24.20.

and ideological interference with employment and promotion (except perhaps through union activity)" (page 88). In his final chapter "Intelligence and Society", Eysenck reports only one example of abuse of IQ tests for job selection: "it has been shown that on occasion white trade unionists in the U.S.A. have insisted on the use of irrelevant IQ tests for job selection in order to keep out black applicants" (page 221).

"Does IQ Measure Intelligence?" is the title of Eysenck's chapter on the validity of the IQ test. "We shall consider some outstanding studies" (page 79) in this chapter, he writes. One of those "outstanding studies" presented was the investigation performed during World War I by American Army psychologists with the Army Alpha, a group test of intelligence. Eysenck gives some of their evidence for the validity of the intelligence test, for example, their finding that illiterate enlisted men performed more poorly on the Army Alpha than literate enlisted men. Eysenck, however, neglects to present any of the items from that IQ test. Here are a few: (a) "Harvard University is in _____"; (b) "Yale University is at _____". Here are a few more: (a) "Why is tennis good exercise?"; (b) "Lob is a term used in _____"; and (c) "a battle in racket very tennis useful is", which is to be rearranged into a sentence and then answered "true" or "false." The Army Alpha was the first IQ test used to classify national and racial groups according to native intelligence. "The great and universally agreed success of these tests caused many other countries to adopt them in later years and presents another external validation criterion for IQ tests as measures of intelligence" (page 83) Eysenck writes.

The book also contains three chapters jointly authored by Fulker and Eysenck: a chapter on heredity, one on environment and a final chapter on socio-economic status. Their evaluation of the evidence supporting an environmentalist position is quite good overall. Their criticisms of the Heber study are reasonable and their presentation of Zajonc's confluence model

is clear and fair. On the other hand, Fulker and Eysenck's arguments for the genetic position are in no way convincing and often misleading.

In his introductory chapter, Eysenck states (page 1): "I have tried to rewrite the relevant chapters in the history of the intelligence testing movement without including Burt's now doubtful data". Whereas Eysenck may have excluded Burt's questionable data from his historical accounts, Fulker and Eysenck present and make rather extensive use of Burt's fabricated numbers in their biometrical analyses. For example, in their analyses of IQ correlations for monozygotic twins reared apart, they include Burt's group-test correlation of 0.77, asserting that "the main criticism [of Burt's data] concerns the individual test scores" (page 109). That statement is false. Indeed, the main criticism concerns his group-test correlation: it remained constant at 0.771 from 1955 to 1966 in spite of large increases in sample size. Fulker and Eysenck also include Burt's questionable IQ correlations in their analyses of data for siblings reared apart (Table 5.4) and for unrelated children reared in the same home (Table 5.5). In their biometrical analyses of educational achievement, they use Burt's correlations for monozygotic twins reared together, for dizygotic twins reared together and for monozygotic twins reared apart (Table 5.14). Their biometrical exercises lead them to conclude that genotype-environment interaction and genotype-environment co-variance are small enough to be ignored. That conclusion contradicts the results of the statistical exercises presented in their final chapter on socio-economic status. The conclusions are as varied as the models.

Near the end of the book, there is an unnumbered chapter bearing the title "Eysenck and the Splitting of the IQ". A careful study of the primary sources reveals that if the IQ was split, it was split by Furneaux. In fact, Furneaux's first publication on this matter was apparently in *Nature* in 1952 (170, 37-38).

Summing up, Eysenck's new book is inappropriate for beginners, but rather entertaining for experts. □

Donald D. Dorfman is Professor of Psychology in the Department of Psychology at the University of Iowa, Iowa City, Iowa.

Comprehensive palaeontology

J.C.W. Cope

The Encyclopedia of Paleontology. Edited by R.W. Fairbridge and D. Jabolonski. Pp.912. (Dowden, Hutchinson and Ross: New York. Distributed by Academic Press: New York and London, 1979.) \$90, £52.50.

THE appearance of a major reference work on palaeontology within the compass of a single volume is indeed welcome. *The Encyclopedia of Paleontology* contains entries from over 120 palaeontologists, mainly from the USA, but with expertise from Europe, Australasia and Canada contributing some 30% of the information. Most authors have contributed only one entry, others have supplied as many as six.

The subject entries are very wide-ranging and cover in considerable detail each group of plant and animal fossils in alphabetical order. In addition to the taxonomic treatment there is a long list of other subjects covered such as biometrics, computer applications in palaeontology, palaeoecology, population dynamics and so on, in which the state of the art has clear exposition. These two categories of entries are complemented by longer discursive entries on such topics as the history of palaeontology (divided into three separate entries, historically), evolution, extinction and other subjects that lend themselves to such treatment.

The entries are well organized and provide a wealth of accurate information; each has cross-references to other entries and, where appropriate, to entries in other volumes of the *Encyclopedia of Earth Sciences*. The reader is directed to further reading by generally well selected and ample references. Occasionally one feels that the author of an entry has not been sufficiently selective in citation of these; as examples of over-zealous quotation of references "Paleoecology of Inland Aquatic Environments" has 110 references and "Radiolaria" almost 120. This surely is not helpful to the average reader seeking direction to further major references.

The references provide at least a general clue to the date of writing of the entry. Some seem to have been written about ten years ago, for although recent references are listed, no reference is made to them in the text. However, the entries in general are up to date; many articles were clearly written around 1976 and references up to 1978 occur commonly. Within the limits imposed by getting such a volume published this seems very reasonable. Where work is dated, it is largely a reflection of how rapidly some aspects of palaeontology have advanced recently.

On first glancing through the book I

wondered whether it had been mis-bound as there are no entries under 'N' — where were nannoplankton, nautiloids, nekton, neoteny? In fact these fears were largely unjustified as most of the above subjects appear elsewhere under other headings and are listed in the extensive index which, a quick calculation suggests, contains close on 5000 subject entries, many with several page references. The index must be criticized, though, in that it sometimes refers to words which are just mentioned in passing. Thus my search for 'neoteny' led to p.34 which merely stated that certain Cretaceous Amphibia were "pedomorphic or neotenic". The index entry for "pedomorphic" only quotes p.34 so that the reader is still none the wiser on what neoteny is, and both index entries are unnecessary. Checks revealed a number of similar superfluous entries. Misprints in the text have led to index entries; thus "Nautiloids" (*sic*) refers to a misprint on p.533 and is quoted by the index separately from "Nautiloids" and "Nautiloidea". "Conchostraca" get separate indexing from "Conchostracans", but the index entry "Cyclostomata" refers to both the vertebrate and bryozoan orders of that name. Clearly the index was not compiled by a palaeontologist, and its value is consequently somewhat diminished.

Although the book is extremely comprehensive in its treatment, I was surprised that scant attention had been paid to the stratigraphical use of fossils. There is an apposite entry on

biostratigraphy by Peter Sylvester-Bradley (one of seven authors who have since died) — but that is all. There is no entry in the index under the word 'zone', and although some systematic entries do refer to stratigraphical value of particular fossil groups, to me this is a major omission.

The book is abundantly illustrated by both half-tone and line illustrations; the great majority of them are first class and contribute significantly to the volume. The high standard of the majority makes one aware of the number which fall short of this standard in some respects; poor reproduction mars several otherwise good figures, and widely disparate sizes and styles of lettering are distracting.

The price of \$90 (or £52.50) seems excessive for a single volume. At half this price the number of purchasers would probably be increased at least tenfold; but the considerable authority and wealth of information contained therein should compel all palaeontologists seriously to consider buying the book. For undergraduates it will provide valuable information and speedy reference to essential reading for essays and project work; for university libraries at least one copy is essential. Despite its faults this is a volume truly worthy of its title and one which is unlikely to be rivalled for a long time. □

Kinetics for chemists

C.F. Wells

Chemical Kinetics and Transport. By P.C. Jordan. Pp.340. (Plenum: New York and London, 1979.) £13.55.

As he states in his preface, and is implied in the title, the author adopts a new style in his treatment of kinetics. The first three chapters are concerned with the fundamentals of the transport of molecules: two deal with the kinetic theory of gases, covering the properties of a collection of gaseous molecules at equilibrium and the transport of molecules; but the third introduces an unusual note for a book on kinetics, a treatment of electrolytic conduction and diffusion. In Chapter 4, the experimental approach to kinetics begins with the determination of rate laws. This is followed by a treatment of stationary state mechanisms, photochemistry and non-stationary state mechanisms. The book is then completed by a consideration of single collisions, the theory of reaction rates and various models for collisional processes.

In its concentration on chemical kinetics from a transport viewpoint, especially in the earlier chapters, the book has a novel

approach. Moreover, much important material is reserved for the problems at the end of each chapter; undergraduate students attempting to follow their more conventional lecture courses with the aid of this book might well become confused. The latter state will probably be increased by what some will regard as a cavalier treatment of elementary rate laws. In Chapter 4, complex ideas are introduced too early: for example, before single rate laws are explored, the problems of the $H_2 + I_2$ and the $H_2 + Br_2$ reactions are stated, and we find a discussion of nanosecond flash photolysis; or, before a discussion of simple orders higher than one, we are plunged into opposed first order reactions. Indeed, in a footnote the reader is referred to a standard text to obtain a detailed understanding of the integrated rate laws. Perhaps this is the most unsatisfactory chapter from an undergraduate point of view, as there are also minor contributions to his confusion. For example, in the section on first order reactions, one finds a jumble of first order and opposed first order reactions; or, on p.90, it is stated that the *first* term in eqn 4.31 vanishes, whereas, in the balance of rates at equilibrium, the first *two* terms disappear. However, if the student survives this chapter, or is assisted

in grasping these basic ideas from other sources, he should be able to proceed readily with the rest of the book. It is, perhaps, unfortunate that some of the theories of reaction rates are not introduced earlier than Chapter 9, so that the ideas developed there could be used *en route*.

Finally, I must introduce what is perhaps a more personal note, although I am sure that others also involved with kinetics in

solution will echo my view. Most general books on kinetics concentrate on the gas phase; understandably so, as here individual molecular processes can be examined in detail. Yet rarely are the complexities of processes in solution dismissed so completely: these are merely referred to very briefly in one paragraph in Chapter 5.

Although I have obviously read this book with a critical eye, I realize, of course, that not everything can be included in a

book of this size. Moreover, I am sure that all who are interested in kinetics will find it stimulating, and this includes undergraduates. It certainly should find a place on library shelves. The format of the book is good and it is well produced; the price is not unreasonable for these days. □

C.F. Wells is Reader in Inorganic Chemistry at the University of Birmingham, UK, and has particular interest in the kinetics of inorganic reactions in solution.

Volcanoes revisited

P.E. Baker

Volcanology. By H. Williams and A. R. McBirney. Pp.397. (Freeman, Cooper & Co.: San Francisco; Blackwell Scientific: Oxford, 1979.) £19.50, \$33.50.

THE authors preface their book with the modest statement that it "... does not purport to offer much that is new; it attempts rather, to summarize for the student and professional geologist current knowledge of volcanoes, particularly their behaviour and physical structure". Despite a superficial resemblance to earlier books on the subject of volcanoes (for example, Macdonald, 1972) and some fairly conventional chapter headings, the approach is essentially rather different. It is a textbook aimed at a specialist readership and largely devoid of dramatic accounts of volcanic eruptions and their consequences. It is written in a lucid and cautious style with every effort being made to adopt a quantitative approach. It attempts a rigorous explanation of volcanic processes and products in terms of established physical principles. There are more descriptive chapters, such as those on "Principal kinds of eruptions" and "Cones, domes and shields", which contain innumerable examples drawn from the authors' wide experience.

They pick their way delicately through the subject, rejecting untenable generalizations and sometimes reconsidering discarded theories. They remind us that the evidence for extraordinary amounts of igneous activity along the axes of oceanic ridge crests is largely circumstantial, and that potassium does not invariably increase towards the interior of continents. Perhaps, also, there is some truth in Daly's theory of the 'vitreous substratum' source for basalt.

At the end of the opening chapter the authors state that, "By far the greatest impetus for studies of igneous processes has come from a growing recognition of the central role they play in nearly all modern tectonic theories". Maps of active volcanoes and plate boundaries appear on the inside covers of the book but can scarcely be regarded as reflecting the

dominant theme of the text. There are references to sea-floor spreading, mid-plate volcanism and subduction of oceanic lithosphere, but the authors appear anxious not to overemphasize the link between volcanism and plate tectonics.

The scope of the book has been carefully restricted and there is, for example, very little discussion of the role of volcanism in the evolution of the Earth, or of volcanism and mineralization. Volcanic activity in the rest of the Solar System is also excluded apart from occasional references and photographs of the martian volcano Olympus Mons and a NASA picture of

volcanic activity on Io.

The book is generously illustrated with many first-class photographs and the occasional indifferent one (for example, Fig. 7-11). The figures are drawn in somewhat varied styles but are not always to the standard one might have expected. Nevertheless, in its description and interpretation of volcanic phenomena this is an excellent book and the authors have certainly succeeded in the task they set themselves. □

P. E. Baker is Professor of Geology at the University of Nottingham, UK.

Methods for studying evolution

R.A. Fisher

Biochemical Systematics and Evolution. By A. Ferguson. Pp.194. (Blackie: Glasgow, 1979.) £14.50.

THE popular image of a taxonomist is of a cantankerous anatomist interminably arguing with an equally cantankerous opponent over some apparently trivial detail. These days, it seems, anatomists are out and biochemical geneticists are in. Cantankerousness and argument are, of course, always with us, but perhaps for those who wish to understand rather than stake their reputations, biochemical systematics can throw some new and useful light on the processes of evolution.

Evolution depends on mutations in DNA, and the basic idea behind biochemical taxonomy is to detect the mutations themselves rather than their effects at several removes. Events overtake us with distressing rapidity these days and it is unfortunate for Dr Ferguson in his book *Biochemical Systematics and Evolution* that he missed the opportunity of mentioning the new technique of restriction mapping, since this allows one to examine the actual gene at first hand. But it is neither the easiest nor the cheapest of methods and for some time to come the electrophoretic comparison of proteins will certainly remain the method of convenience, if not of choice. It involves the

investigation of the gene product rather than the gene, but it is much closer to the ideal than the morphometric comparisons of anatomists.

Electrophoresis is a well established and well described technique and much has been published on the interpretation of protein separations and zymograms. It is a pity, therefore, that, having stated that the aim of this book "is to provide the reader with the necessary background to the principles and practice of electrophoresis", the author does not make a better job of it. If this really was his aim, the sections on methods are too brief and in parts misleading. If one were, for example, to try electrophoresis according to the diagram on page 36, one would fail. Electrical contact between the gel and the electrodes is apparently prevented by a plastic film. The chapter which deals with the interpretation of isozyme patterns is again too brief and sometimes inaccurate. In particular, the origins of isozymes could have been more clearly explained.

The second half of the book deals with the interpretation of data, and here Dr Ferguson seems to be on much more familiar territory. He deals concisely and clearly with the various ways of measuring evolutionary distance and the mathematical examples are well explained and easy to follow. It is this part of the book that will really be of use to the audience for which it is intended, "advanced undergraduate and postgraduate students". □

R.A. Fisher is Head of the Comparative Genetics Section in the Nuffield Laboratories of Comparative Medicine at the London Zoo, UK.

Metals and gases

J. M. Thomas

Chemistry of the Metal-Gas Interface. By M.W. Roberts and C.S. McKee. Pp.594. Clarendon Press/Oxford University Press: Oxford, 1979. £26.

MUCH thought has gone into the planning and writing of this commendable book. Where does one begin in the ordering of a topic that is so expansive and multifaceted? Short summaries, however refreshing, tend to distort the truth. Usually they do not faithfully reflect the vast ramifying nature of a complex and important subject. But comprehensive and detailed surveys dull the mind, provoke the thought that "he who increases knowledge increases sorrow" and inevitably tend to bury important signals in oceans of noise.

A book that runs to nearly 600 pages may at first sight appear to belong to the second of these two categories. Not at all. It is so expertly organized and sub-divided into compact but cleanly dove-tailed components that the 13 chapters make for informative and pleasant reading. The first two chapters neatly summarize the basic concepts of the surface chemistry and crystallography of solids. The next two present authoritative accounts of low energy electron diffraction (LEED) for surface characterization, and the various branches of electron spectroscopy (X-ray or UV induced photoelectron spectroscopy, Auger electron spectroscopy) for the characterization of the energy levels of adsorbates and energy levels or bands of adsorbents. In both these topics, the authors, especially Roberts, have made several original contributions. A further two chapters continue on the theme of surface identification and characterization of the adsorbed linkages; one is devoted to the direct spectroscopic approach (infrared and Raman), the other to a short survey of the surface kinetics involved in such processes as molecular beam scattering. There is also a useful account of the kinetic formulations required to rationalize observed rates of adsorption and desorption as measured by, for example, dynamic mass spectrometry.

Following a short illuminating treatment of physical adsorption at 'clean' metal surfaces and the rudiments of surface diffusion, the book devotes four chapters (nearly 200 pages) to gas reactions at the (predominantly) single crystal faces of various transition and refractory metals — for example W(211), Pt(111), Cu(100), and Ni(111). Almost exclusive attention is paid to the behaviour of the diatomic gases O₂, H₂, CO and N₂; metal adsorption on metals is considered; and the particular activity of stepped surfaces (first clearly identified by Somorjai) is reviewed. This section of the book succeeds admirably in placing recent developments in the context

of earlier endeavour, one of the declared aims of the authors. This section is likely to serve as a valuable quarry for all those interested in retrieving critically digested and reliable information of metal interaction with simple gases.

The final chapter on the impact of new experimental developments on heterogeneous catalysis is a little disappointing. Greater emphasis could have been given to the comparability of certain processes, such as the activation of CO and O₂ in homogeneous and heterogeneous systems. The recent work of Muetterties *et al.* (1979) on metal cluster compounds as models for heterogeneous catalysts, and analogous studies by Bradshaw *et al.* (1979) on Ru₃(CO)₁₂, draw attention to the kinship between the exterior of metal clusters on the one hand and exposed metal surfaces — for example Ru(001) — on the other. Similarities in densities of state alone (as exist between tungsten carbide and platinum at their Fermi levels) are not likely to be the sole cause for the observed,

uncanny similarity in catalytic activity of these materials as reported by Levy and Boudart in 1973.

One may point to a few errors of omission: no mention is made of EXAFS nor of the remarkable studies made (by Yagi and others) on reflection electron diffraction/microscopy of clean and contaminated 'elemental' surfaces. EXAFS in particular, with its ability to yield bond distances, coordination numbers and mean square fluctuations of neighbouring atoms, is already making a valuable contribution to our understanding of solid surfaces. But these are very recent advances. The authors had to call a halt somewhere. How many books in this field published less than a decade ago discussed XPS, UPS, AES and several other techniques which are so impressively paraded in this volume? □

J. M. Thomas is Professor and Head of Department of the Department of Physical Chemistry, University of Cambridge, UK.

Anion determination

H.M.N.H. Irving

Handbook of Anion Determination. By W.J. Williams. Pp.630. (Butterworths: London, Boston, Sydney and Toronto, 1979.) \$45.

ANALYSTS familiar with Sandell's *Colorimetric Determination of Trace Metals* have long felt the need for an equally authoritative text on anions. Faced with the need to determine a specific anion (and the present book deals with some 75 different ones), we must select one from among the many procedures which may have been published after due consideration of the accuracy and precision required, the length and cost of a determination, whether a few or a large number of samples will be presented, and the apparatus and the operator's skill needed.

The author deals in order with 36 common anions from acetate to vanadate, then with 14 halogen anions, 14 phosphorus oxyanions, and finally 11 sulphur anions. For each anion there is a well referenced review of separation and concentration procedures (which include distillation, liquid-liquid extraction, chromatography and ion-exchange, precipitation, adsorption and special methods as appropriate). Then follows a review of determinations by gravimetric, titrimetric, spectrophotometric and electroanalytical methods emphasizing techniques such as infrared spectroscopy, the use of ion-selective electrodes, atomic absorption and fluorescence, radiometry and miscel-

laneous methods. The reader must usually make his own choice of procedure but in many cases experimental details of selected determinations are given in full. Where reference is made to special apparatus there are excellent line drawings and great pains have been taken to give the structures of the many organic reagents used; their lay-out is, however, inconsistent in that methylene blue is shown as a sulphonium cation on page 550 and as an ammonium salt on page 576, and the formulae for its fluoroborate complex on page 34 is patently incorrect as must be those of the ternary zirconium-calcein blue-F⁻ complex on page 369 and nitron on page 123. Dyes derived from triphenyl methane may sometimes appear with a carbonium ion, a quinonoid structure, or a lactone ring; ionization of a salt is sometimes explicit but the older presentation, for example, CH₃C₆H₄SO NC1Na, is typical of other formulae in which salt formation must be understood.

But this is purely carping at points which will not diminish the great value of this book to practising analysts who have long had to rely on a miscellany of publications for material that is gathered together here in a single comprehensive book. I particularly liked the full and critical discussions of the determination of phosphorus as molybdo- and vanadophosphate, and the determination of halides, alone and in admixture. Despite the price, no analyst or teacher of inorganic chemistry can afford not to have this fine new undertaking within his easy reach. □

H.M.N.H. Irving, formerly Professor of Structural and Inorganic Chemistry at Leeds University, is now Professor of Analytical Science at the University of Cape Town.

24 April 1980

Are books too expensive?

We love books not merely for what's in them. Books feel good, even smell good. Touching them, we rub the grain of their bindings, we skate our fingers across fine paper, we run our thumbs through pages as if they were guitar strings. They feel good whether they are words by Flaubert or encyclopaedias of pharmacology.

In a bookshop, we can rest our arm on a shelf lost in the art of Chinese porcelains as we face a stack of paperback jackets glowing with sex. We may dash into the shop to get out of the rain, and yet walk out with a storm of ideas, provoked by a chapter heading.

Until quite recently, perhaps our only regret, stimulated by an encounter with books in a bookshop, was the certainty that one life could never give us enough time to read all the books worth reading. There once was a time we could pay our bill and walk out into the street with a few titles under our arm, all for the price of the lunch skipped that afternoon.

Today, of course, the prices confound the pleasures of buying books. What we once could purchase for the price of a skipped lunch, now costs us the equivalent of a dinner in a first-class restaurant. And when we get the bill for scholarly books the tally looks like what we might have expected to spend for a meal in a great French restaurant.

Book reviewers for this periodical often complain about the high prices. Young scientists despair at ever being able to afford them. And the rest of us grumble, often attributing the prices to the greed of publishers. What is to be done? Some argue that if publishers of scientific and technical books showed some restraint, restricting the number of symposia or limiting the output of House titles which are of interest only to narrow specialists, then prices would fall. According to this claim the prices of scholarly books are inversely proportional to the population served. Consequently, publishers must choose books for larger audiences.

There are those who suggest that the best way of lowering the prices of scholarly books is to eliminate unnecessary duplication of titles. Take, for example, the book displays at the Federation of American Societies for Experimental Biology meeting in California a week ago, where more than two dozen publishers exhibited their books. Biologists interested in a book on, let us say, interferon, could choose from among five or six new volumes on the subject, each one from a different publisher along the aisle. We would turn fewer trees to pulp and prices would fall if only a single publisher issued a book on each topic, or so this argument goes.

The difficulty with all these solutions is that the regulation of the science book publishing industry would be much like regulating science itself. Scientific literature rides the caboose on the train of science. Where science goes, publishers inevitably follow.

In order to make any of these proposals work, we will require men and women of great vision. They will need, for example, to choose from among the hundreds of symposia held each year those which should be privileged to appear in print. They will need to determine which are destined to be the classics, to be used in classrooms and laboratories over the next decade, and which should end with the after-dinner speech at the closing banquet.

Or consider those books which might never have been published had someone thought them too specialized. Who among us has the power to predict which area of investigation, now at the periphery of science, will some day emerge at the core?

And as for the proliferation of similar titles on the same subject: can any of us pick the author who will write the best book?

It is true that the rain of books falls most heavily on the libraries. With each slash of the budget, librarians can afford to buy fewer books. As libraries, traditionally the principal customers for scholarly publications, purchase still fewer titles, publishers are forced to charge yet higher prices. And so with each twist of the inflationary spiral, libraries and publishers alike struggle to breathe.

Yet neither inflation nor the ineluctable way in which science unfolds offers absolution to the publishers. We all recognize those who maintain their dignity, even under the strain of conflicting market forces, by their good books. There are those publishers, however, who acknowledge that in order to feed their hungry publishing mill, they must grind out lots of books — good or bad, it hardly makes any difference. Some publishers don't even blush when they compare their own books with sausages or shoelaces.

When will it all end? When will we be able to walk into our local bookshop again, pull a volume off the shelf, and pay the bill without anxiety? For the moment the outlook is grim and will remain so at least until the pace of worldwide inflation slackens. Publishers are not immune to the rapid rise in costs experienced nearly everywhere. Paper, binding, typesetting, distribution and advertising costs are likely to scramble to still higher peaks as costs climb generally.

When we learn how to control an economy gone berserk, we may learn how to control the prices of books. □

United States

Threat to marine science lessens

The new draft of the Law of the Sea Treaty has eased potential restrictions on international marine research. But not all nations are entirely happy with the result. **David Dickson** reports from New York

PRESSURE coming largely from the US scientific community has resulted in a number of changes in the proposed Law of the Sea Treaty, under debate in the United Nations since the early 1970s. The changes are aimed at easing potential restrictions on the conduct of scientific research in regions of the oceans directly controlled by coastal states.

Few of those involved in the negotiations are entirely happy with the outcome. Many nations with large off-shore resource deposits — in particular Canada and some of the Latin American states — would have preferred to stay with the strict controls over research initially proposed, while the scientists of other nations would have liked greater movement in the direction of free scientific enquiry.

Both admit, however, that some compromise between the goals of scientific inquiry and the political and commercial demands of resource management has become necessary. And the changes which have been introduced into a new draft of the treaty, approved at the end of a negotiating session in New York earlier this month, will go to Geneva in the summer for what is hoped to be the final meeting before the treaty is agreed and signed early next year.

Earlier drafts proposed giving coastal states almost absolute authority over research carried out in waters under their control had brought strong protests from scientists who claimed that this would be a direct restriction to the freedom of scientific inquiry.

One of the strongest criticisms came from the US National Academy of Sciences, whose ocean policy committee issued a statement in 1977 warning that unless changes were made in the draft text, the proposed treaty would "cripple future marine scientific research" critical to the survival of the oceans and of mankind.

Since then, the treaty's provisions have been modified as negotiators have attempted to tread a delicate path between commercial and scientific interests, the two connected by the fact that information about resource deposits — for example oil and natural gas — can have important commercial implications when licensing or exploration rights are being considered.

At an early stage, for example, the US dropped its demands that one guiding principle should be the "obligations" of nations to provide for the interests of scientific researchers. It has now been accepted that research within a 200-mile

economic zone and on the continental shelf can only be carried out with the consent of the coastal state, but with the understanding that such consent must be granted when the research project is conducted for peaceful purposes and fulfills other specified criteria.

There have also been modifications to the rules governing the publication of research findings. Previously these would have been strictly controlled by the coastal states involved, triggering complaints of potential censorship. Now the conditions under which permission to publish can be refused have been tightly specified, and a researcher must be told of these conditions before his project begins.

Tentative agreement on the three main outstanding issues of interpretation was reached during the New York negotiations, based largely on proposals put to a working committee by its chairman Dr Alexandrov Yankov of Bulgaria, which the US delegation had already indicated it was prepared to support.

Firstly, there was agreement that disputes over the withholding of consent should be referred to compulsory conciliation, where previously there had been no scope for such a decision to be appealed.

There was also agreement that if a coastal state considers that research to which it has given its consent is carried out in a way that violates the treaty, it now has to give the research worker time to amend the procedures, and no longer has the power summarily to terminate the research project.

Finally, the new draft contains revised wording about the conditions under which a coastal state with a wide continental shelf can refuse permission for research in areas of the shelf outside the 200-mile limit otherwise agreed as the limit of economic responsibility.

Here the wording finally agreed was that permission to carry out research could only be refused in situations where detailed exploitation or exploratory operations were already occurring, or were about to occur within a reasonable period of time.

Negotiators in New York spent considerable time over the wording of this paragraph, since ambiguity over the meaning of "detailed" exploration left a number of countries unhappy that, unless test drills were virtually in place, they could not deny scientists access to areas in which commercially valuable deposits might lie.

Indeed, in the final plenary session of the New York meeting the Canadian delegate

argued that the conference might be building "potentially serious interpretation problems" into the proposed treaty with such wording, adding that "my delegation would have much preferred a solution with more specific concrete provisions clearly affirming the rights of coastal states relating to the conduct of marine scientific research on the continental shelf beyond 200 miles."

But US scientists who, with colleagues from the Federal Republic of Germany, have been pushing strongly to ease the initial restrictions, feel that the changes have made the treaty, if not better, at least less unacceptable than previously.

"We still do not feel that the deal on scientific research is as good as it should be," says Dr John Knauss, Dean of Oceanography at the University of Rhode Island. But he adds: "It's now a question of whether we have a treaty with these amendments or no treaty at all". Others feel that, although the scientific community is unlikely to back the treaty actively, it is also unlikely to oppose it in its present form.

Despite agreement in New York on almost 90% of the proposed text for the Final Law of the Sea, some major problems remain before the treaty can be signed. One of the largest is the composition of the council for the International Sea-Bed Authority responsible for allocating mining rights and determining the conditions under which resources can be exploited.

Here the developed countries, keen that the activities of their industries should experience minimal restrictions, are urging that only five of the council's 35 members should be able to prevent a mining contract from being refused — in other words, should have power to grant a contract. (Five of the western developed countries — US, Japan, West Germany, France and the UK — would have seats on the council.)

In contrast, the developing countries are arguing that it would be more democratic for nine votes to be required for a contract to be awarded, and that a similar number would also be sufficient to block the award of a contract, numbers which the western countries feel could throw them in to an uncomfortable alliance with the Soviet-bloc.

Despite such disagreement, UN officials still hope that sufficient progress has been made to conclude the final version of the treaty during the Geneva meeting, and for it to be signed next spring. The next problem will be getting it accepted. And in the US this means convincing the Senate, responsible for ratifying all foreign treaties, that the changes have been sufficient to meet the previously expressed concerns. □

US/UK collaboration proposed for breeder technology study

A US congressional committee has approved funds for a joint US/UK study of the future development of liquid metal fast breeder reactor (LMFBR) technology, intended as part of the current programme to build such a reactor at Clinch River in Tennessee.

Precise details on how the money would be spent have yet to be determined. And whether the joint study manages to get off the ground depends largely on how much support can be generated for it in Congress and the administration.

However if the funding is approved the study would, according to US officials, provide a way of formalising the existing interchange of information between nuclear scientists in the two countries, perhaps leading to agreement on efforts to avoid duplication and to help in filling gaps in each other's programmes.

The joint study has been proposed by Energy Production Subcommittee of the House Committee on Science and Technology, which has consistently — and so far successfully — opposed President Carter's attempts since 1977 to terminate the Clinch River project.

Disagreeing with the President that fast breeder development should be delayed either because of the increased risks of nuclear proliferation or because of declining forecasts of energy demands, the subcommittee last year recommended \$183 million be spent in 1980 on the project, which had been dropped entirely from the Department of Energy's budget request.

Clinch River: technical team to cooperate with UK scientists.

Congress subsequently approved spending \$172 million on the project.

This year, after the President had again recommended terminating the project in the budget for 1981, the subcommittee is proposing a budget of \$155 million. And of this, "up to \$15 million" would be for a joint US/UK study with particular emphasis on future fast breeder reactors.

Introducing an amendment to the DOE's budget request, Mrs Marilyn Lloyd Bouquard of Tennessee said that such an effort would be in line with the recommendations made in the final report of the International Nuclear Fuel Cycle Evaluation (INFCE). Ultimately, she said, it would lower the cost of fast breeders.

According to Mrs Bouquard, the proposed joint study would as far as

possible draw upon the existing technical team, design information and data base of the Clinch River project, whose design is virtually finished but for which the DOE has not requested a construction permit.

A spokesman for the United Kingdom Atomic Energy Authority said that already agreement to exchange facilities with the US on fast breeder technology had been reached in September 1979: the UK will subject fuel assemblies to "gross abuses" in the US 'TREAT' test facility, while US researchers will have some access to the prototype fast reactor at Dounreay. But negotiations with the US, and France and Germany, for more extensive exchange on the scale envisaged by the congressional sub-committee were "at a very early stage", pending firm British commitment to a fast reactor policy. □

Panel urges research on tropics before forests disappear

A substantial acceleration of the pace of compiling biological inventories of tropical plants and animals, and a four to five-fold increase in the number of appropriately trained taxonomists to help achieve this, have been recommended in a report on tropical biology by a panel of the National Academy of Sciences. The report, shortly to be published in Washington, warns of the increasingly rapid disappearance of the world's forests.

The panel also lists a number of areas of tropical forests, including the coastal forests of Ecuador, eastern and southern Brazilian Amazonia, and western and southern Cameroon, which it says should receive particular attention by taxonomists over the next 5 to 10 years, since they contain little-known biota in immediate danger of extinction.

And it recommends that a comprehensive laboratory should be established in Puerto Rico as a centre for research and training in tropical physiological plant ecology.

"The creation of such a laboratory appears to be critical for the establishment of a field of investigation that is poorly developed in the tropics. Such investigation appears to offer a great deal

both in scientific and societal rewards" the report says.

The report was prepared by the Committee on Research Priorities in Tropical Biology of the Academy's National Research Council, chaired by Dr Peter H Raven of Missouri Botanical Gardens, St Louis, Missouri.

Speaking in Washington last week, Dr Raven pointed out that less than 10% of the Earth's estimated four to five million species have yet been properly classified, but that while scientific knowledge of tropical ecosystems was virtually non-existent, these areas were being destroyed by population pressures and other demands at an alarming rate.

"I am convinced that 95% of the forests will be converted within 25 to 30 years", said Dr Raven, whose panel predicted that by the close of the century the only extensive areas of undisturbed forest remaining would probably be chiefly those in the western Brazilian Amazonia and in Central Africa. However even those, it says, will probably only persist "for a few more decades".

Dr Raven's conclusions were supported by Dr Norman Myers, author of a study *Conservation of Tropical Moist Forests*

commissioned by the panel, which provides a detailed account of the areas currently under threat.

According to Dr Myers, about three quarters of the tropical forests that have already been lost through the actions of millions of forest farmers over the world, who have been able to gain access to the heart of forested areas by using logging trails.

The Academy report warns that if the destruction of the forests continues at the present rate until the next century, the result will be not only widespread human misery and "alterations to the course of evolution", but also the loss of potentially useful knowledge about plant and animal species that might have been used to mitigate some of the consequences of such development.

"This knowledge is therefore not only of theoretical importance, but has critical application of benefit to human welfare both in the tropical countries themselves and throughout the world. If tropical research is allowed to continue at its present level, it will contribute only in a minor way to the solution of the human and scientific problems to which we have alluded" the report says. **David Dickson**

Offshore windmills: can they help conserve fossil fuel?

UK energy

The prospect for ocean-going windmills

THE generation of electricity from windmills sited off the coast of Britain is technically feasible and very likely economic, according to a recent study on the assessment of offshore siting of wind turbine generators commissioned by the UK Department of Energy.

Large arrays of land-based windmills are unattractive in the UK because of the lack of large areas of unpopulated hilly land. However, the UK does have the advantage of a wide continental shelf covered by shallow waters; it also has considerable experience in offshore engineering gained from the exploitation of oil and gas from the North Sea. The study, which should be published in full later this year, has identified several possible sites where the structures for offshore windmills could be built with existing technology. A synopsis of it was presented by P. B. Simpson and D. Lindley of Taywood Engineering — the main contractor for the study — at a meeting of the British Wind Energy Association last week.

Clusters of up to 200 offshore windmills spread over an area of about 60km² could be capable of providing 600MW of electricity to the national grid, the study concludes. Their main economic value would be in the savings they would contribute to the burning of fossil fuels. Machines with 100m diameter turbines placed in areas with an annual mean wind speed of 10m/sec could generate electricity at a cost of 3.4p/kWh — compared to the current cost of about 1.5 p/kWh of generating electricity from a coal fired power station. A similar field of 80m diameter turbines and an annual mean wind speed of 9.5 m/sec could generate electricity at a cost of 5.1 p/kWh.

Unlike conventional power stations,

wind turbines have no fuel costs. The only costs to be factored into calculations of cost per kWh, therefore, are maintenance and capital costs. Moving offshore increases both considerably. According to Simpson and Lindley, the cost of the support structure for one wind turbine (excluding the turbine itself) would be £3 million. One machine would cost £34,000 a year to maintain; and support facilities onshore would have to be built at a cost of £25 million for a 200 machine cluster. Transmission costs for a 600 MWe cluster they estimated to be £171-189/kW — four times that for a conventional 600MWe power station. Construction period and operation time were assumed to be eight and 20 years respectively. They gave no total capital cost for a 200 machine cluster but Dr Peter Musgrove of Reading University, who also participated in the study, believes that a cluster with a generating capacity of up to 1000MWe could be built for roughly the same price of a conventional power station of the same capacity. All costs in the study were at mid-1979 prices.

Most of the capital cost of building wind turbines offshore would be taken up by building support structures which could withstand the rigours of the sea. So the greater the generating capacity of each machine, the more cost effective it would be. Wind turbine diameter is one of the three main factors affecting generating capacity, according to Simpson and Lindley. The other two are mean and rated wind speeds and cluster configuration. Machines spaced at anything less than fifteen turbine diameters are considerably less efficient than individual machines. In the particular sites considered in the study, mean water depth (10-25m), height of

turbine axis above the water (1-1.5×turbine diameter) and distance offshore (5-25 km) had only secondary effects.

These conclusions are based on the detailed analysis of three sites — Burnham Flats in the Wash approaches, Shell Flat off Morecambe Bay and Carmarthen Bay — chosen out of an initial 17 on technical and economic grounds. Lindsay and Simpson stress that these sites are not to be seen as automatic choices for future projects. The study did not include the question of amenity, they say, because it was felt that detailed proposals would be needed first. However, it did assume that all possible sites should be at least 5km from the coast.

If wind power is developed vigorously, thinks Dr Musgrove, it could match the development of nuclear power over the past 25 years and contribute 20% of electricity supply by the year 2000. It should be possible, he says, to build several arrays each containing 200 machines of 100m turbine diameter and capable of generating 5MW each. The net result of each array would be equivalent to one 1000 MW power station operating with a 35% load factor. Variability in wind speed would not be much of a problem because at offshore sites the wind is fairly constant over short periods. The greatest variation is seasonal but this has the advantage that the strongest wind is in winter.

To realise this potential, says Dr Musgrove, the UK should be prepared to support a government funded programme of at least £5 million per year on wind energy research for the next decade, compared to the £½ million spent last year by the Department of Energy; otherwise there is a danger that Britain will fall behind the US, Holland and Germany, its chief competitors in this field. The US and Germany are already building horizontal wind turbines of diameter up to 140m, whereas the UK has not yet received approval to build a 60m diameter horizontal axis machine even though £½ million has been spent on its design.

Dr Musgrove, however, is an advocate of vertical rather than horizontal axis machines. The problem with horizontal axis machines, he says, is that the blades are subjected to gravity loads acting in different directions and this considerably limits their size. A vertical axis machine would not have this problem and could be built to much greater diameters.

So far, however, the UK has gone no further than to design a 25m, 100-150kW vertical axis machine. A decision on further funding for that is also expected later this year. The next six months, therefore, will be decisive for the future of UK wind energy, thinks Dr Musgrove. Not only does a decision have to be taken on what should be done as a result of the offshore study, but decisions have also to be taken on the future of the 60m horizontal and 25m vertical axis designs.

Judy Redfearn

United Kingdom

Science Research Council cuts top grants

BRITAIN'S Science Research Council has been forced to reject £2.2 million worth of "alpha" quality applications for university research, a spokesman said last week.

The Science Board, one of four grant-allocating boards of the SRC (the others are Astronomy Space and Radio, Nuclear Physics and Engineering), meets three times a year to decide allocations. At its first meeting this year the board managed to stave off cuts, except for all "beta" applications — worthy research which "wouldn't disgrace the British taxpayer" but without the star quality of the alphas. Beta research — about a quarter of all applications — has not been funded for the past three years.

But at the Science Board's recent second allocation of the year, it proved impossible to avoid cuts even in the alphas. A total application for £7.1 million was cut back to £4.9 million by applying an across-the-board 30% cut to all of the Board's 10 committees. The committees range from basic biology, maths, physics, and chemistry to science-based archaeology and cognitive science.

The Board spends some £16 million annually on direct research grants to universities, compared to about £3 million each for the astronomy and nuclear boards and £19 million for the engineering board. The cuts thus represent a substantial loss of direct science spending in universities.

"We are most worried about the very few people now going in to new posts in universities" said the spokesman. "We used to be able to be a little generous and allow for the enthusiasm of these 27 to 30 year olds. But there is no more room for the benefit of the doubt. We are cut to the bone."

However, the picture shows some signs of improvement. At the next meeting, the Science Board hopes to have to cut only 15 to 20% of its "alpha" applications, as a result of money beginning to be freed from long term commitments. These are principally the spallation neutron source being built at the Rutherford Laboratory, the synchrotron radiation source at Daresbury, and Britain's one third share of the Institut Laue Langevin at Grenoble. The major part of the spending on these facilities should be over in three years, releasing some £2-3 million a year; and as grants run typically over three years, some of these savings can begin to be accounted now. □

Thaumatococcus . . . sweet discovery

Gene machining sweeter gum

TATE and Lyle, the British sugar manufacturers, are to apply recombinant DNA techniques to improve production of the protein thaumatin — a substance 2,500 times sweeter than a 10% sugar solution.

Thaumatococcus is produced by the berries of the African bush *Thaumatococcus daniellii*. It was discovered in a 1968 survey for new sweeteners conducted by the UK Ministry of Agriculture; and already Tate and Lyle have plantations of the bush in Ghana, Liberia, and Malaysia producing "hundreds of tonnes" of the berries annually.

One tonne of berries produces a kilogramme of thaumatin, which at present is sold only in Japan. Japan accepts thaumatin as a "natural product" which does not require toxicity testing; other

countries require extensive toxicity tests. An application on the basis of preliminary tests by Tate and Lyle has been with the UK Ministry of Agriculture, Fisheries and Foods since January 1978.

Dr John Higginbotham, who is in charge of the thaumatin project at Tate and Lyle's Reading laboratory, estimated future markets as a tonne annually to Japan, with five times that in Europe and ten times in the US. This 150-fold increase could come from increasing the cultivated area of *Thaumatococcus* — but the plant will only propagate in hot climates. The company could avoid "politically uncertain" crops in Third World countries if it could transfer the gene for thaumatin production from the plant to a bacterium, which could then be grown in fermenters anywhere.

Professor Ken Stacey, director of the biological laboratory of the University of Kent, has taken on the task, backed by a £90,000 grant for three years. Professor Stacey thinks three years should see them through to expression of the gene; development of a production process will take longer.

The first task is to isolate the relevant messenger RNA, he says. And ultimately there may be the problem that the bacterial cytoplasm will not encourage the formation of the eight disulphide bonds required in the folded thaumatin molecule. Thaumatococcus has a molecular weight of some 20,000, around three times that of insulin.

The size of the molecule, compared to that of sugar, is one drawback to its wide application as a sugar substitute, said Dr Higginbotham. It is less mobile on the tongue, and so takes "a second or two" to register its sweetness. Lemonade, for example, sweetened with thaumatin, would taste first bitter (from the citric acid) and then sweet (from the thaumatin). Consequently it is only likely to be used in substances like toothpaste, which stay in the mouth for a long time. □

France

Reprocessing plant close to disaster?

THE French nuclear reprocessing plant at Cap de la Hague, near Cherbourg, apparently lost all electrical power on 16 April for an hour, closing down cooling systems on high active waste tanks and ventilation over nitric-acid filled reprocessing vats. Full power was not achieved for another 11 hours.

According to a report in the *Guardian*, a major catastrophe was averted only because the plant was not yet in full production. Auxiliary power was not available because the failure was caused by a fire in a transformer room through which passed both the main and back up circuits. Pierre Tanguy, Head of Safety at the French Atomic Energy Commission (CEA) told *Nature* last week that the back up circuit was not necessarily at fault but "it

would be looked at".

According to Tanguy, there was no radioactive release and no hazard to the workforce or environment. "It was nothing serious" he said. However the French union the Confédération Française Démocratique du Travail have argued in a booklet "Le Dossier Electronucléaire" that a particular danger in reprocessing is "the possibility of cooling caused by the failure of the main and back-up electricity supply". But the accident was not predicted in any official safety studies, says the *Guardian*.

COGEMA, the government-owned company which controls reprocessing in France, have said that the plant would be open again this week.

Robert Walgate

NEWS IN BRIEF

Fusion research boost at Karlsruhe

GERMANY'S nuclear research centre at Karlsruhe, which has for a long period concentrated on fast breeder reactors, has begun to turn its attention to fusion. In its 1980-3 budget Karlsruhe has allowed a 61.5% increase in fusion spending, taking it from 22.6 million DM in 1980 to 36.5 million DM in 1983.

The centre will concentrate on the technology of complete fusion reactors rather than on basic plasma physics, says a report in *Wissenschaft, Wirtschaft, Politik*. It will also construct a superconducting coil for a torus to be built at Oak Ridge National Laboratory in the US, and make some "exploratory studies" of deuterium-tritium inertial confinement.

The greatest effort at Karlsruhe will still be on the fast breeder, but the programme will increase only by 3.5%. The total Karlsruhe budget will increase by 16% from 336 million DM in 1980 to 388 million DM in 1983.

Superconducting technology, on the other hand, will be cut by 5.4%. The main sufferer will be high current superconductivity.

May launch for two Ariane satellites

THE second test flight of the Ariane launcher to place two satellites in orbit will take place between 20-30 May from Kourou, French Guiana, the European Space Agency and the French Centre National d'Etudes Spatiales announced last week. The actual three-hour launch will occur between 1130-1430 hours GMT.

Preparations for the launch, begun on 2 April, are going ahead on schedule following the arrival of the L02 launcher at Kourou. The first, second and third stages of the launcher were erected on 4 April, 8 April and 14 April respectively. The equipment bay was placed in position on 15 April.

The plan of operations has been streamlined compared to the first flight test, L01, thereby reducing the preparation time by about a month. The satellites to be placed in orbit are Firewheel, a scientific satellite designed by the Max Planck Institute, and Oscar 9, a satellite designed by the German Branch of the Radio Amateur Satellite Corporation.

Space shuttle engine test successful

THE National Aeronautics and Space Administration's space shuttle, plagued by a succession of technical problems, received some good news last week when it was reported that the shuttle's engines had

been successfully tested at full power for six minutes. In a static firing test carried out at NASA's National Space Technology Laboratories at Bay St Louis, in Mississippi, the engine operated for a total of 10 minutes and ten seconds — including the first sustained operation at its full 109% of rated power — and met all the test objectives.

Meanwhile the agency is asking private industry to perform a study of thermal protection systems which might be developed as an alternative to the present ceramic tiles which have been giving the shuttle programme severe difficulties and have caused the delay of the first flight to late next year at earliest. The purpose is to find whether any recent technological advances in reusable surface insulation might provide an acceptable alternative. The industry study will evaluate metallic and reinforced carbon compounds.

French commission approves Plogoff reactor

THE three commissioners charged with conducting the nuclear power inquiry in Plogoff recommended last week that the government go ahead with its plans to construct twin nuclear power stations on the scenic Brittany coastline of Cap Sizun. The commissioners based their decision on the observations of 121 people who visited the government's exhibits staged in "town hall annexes" set up after the mayors of the four affected communes, Plogoff, Primelin, Goulien, and Cleden-Cap-Sizun

had refused the government access to their town halls.

The "town hall annexes" had been the subject of militant protest during the 6-week exhibit from 31 January to 14 March, and had to be surrounded by mobile police forces who engaged in battles with the daily demonstrations of up to 20,000 people that were called "la messe" (the Mass) by the protestors. Only 212 of the estimated 60,000 people in the region visited the mobile vans.

French environmental groups attacked the decision, calling the public inquiry a

"grotesque hypocrisy". M. Phillipe Marchand, deputy from Charente-Maritime and Socialist Party spokesman for energy criticised the commission for "ignoring the fact that almost the entire population is opposed to the project and that a number of scientists have denounced the insufficiency and quasi-falsification of the impact studies".

A group of 20 political organizations, trade unions and ecological groups in Finistère, seat of the regional prefecture, denounced "the police over-reaction" during the inquiry and have called for the resignation of the chief of police of Quimper and the dissolution of the prefecture's riot police as "a permanent menace against the right to demonstrate". The French Council of State will take its decision on the reactors after a delay of up to eight months.

Energy conservation cut back

ENERGY conservation spending at the UK Department of the Environment, which is responsible for building regulations, will be £31.1 million for 1980-81, according to a ministerial statement in the House of Commons. This is to be compared with an allocation of £67.6 million in 1979-80, of which £51.6 million was spent. There is no longer a specific allocation for the insulation of housing built by local authorities, said the minister, and grants for assistance with private home insulation have been reduced "to reflect the pattern of demand". According to Gerald Leach's *A low Energy Strategy for the UK*, around 50% of end-use energy is used for low grade heat. A large part of this is used to heat buildings.

British PWR application imminent

A "letter of intent" to build a Westinghouse pressurized water reactor will be issued shortly, the chairman of Britain's Central Electricity Generating Board, Mr Glyn England, said last week. The letter will release "an avalanche" of technical information from Westinghouse, said Mr England. Detailed design of the reactor would then go on within the National Nuclear Corporation, in close consultation with the CEBG and the Nuclear Installations Inspectorate (which will report on safety). A firm application for consent to build would then go to the government at the end of 1981, followed shortly after by the NII safety report. The CEBG hope that the promised public inquiry on the PWR would be held by the spring of 1982, and that if the results are favourable, construction could begin at the end of that year.

On the beach . . . Westinghouse's Angra I (left) and the Angra II site (right)

The politics of power in Brazil

WITH an electricity demand of 25,000 MW and a hydroelectric potential above 200,000 MW — the Brazilian government went ahead in 1975 with a multi-billion dollar nuclear programme. Brazil's nuclear programme is now years behind schedule and in a state of general disarray, as foreign loans are used up and open dissent appears at all levels. **Maurice Bazin** reports

THE original plan, drawn up in the first half of the 1970s, in the heyday of the fanfared Brazilian "economic miracle", called for 60 nuclear power plants, producing 75,000 MW, by the year 2000. It reflected the mood for grandiose projects of that period — the Brazilian version of the American conquest of the West — symbolized by the construction of the Transamazonian Highway. The launching of these projects coincided with a period of harsh military rule and total press censorship. No sobering criticism could be heard and only the promises of the "miracle" were allowed exposure.

Today, the Transamazonian Highway has not brought the expected development. On the contrary, it has only destroyed what was there already. As for the nuclear plan, it has been reduced to eight plants by the year 2000, and there are many calls for a stop to the programme after three plants have been brought into operation, in 1995.

Nuclear energy does not have a good reputation in Brazil. The first attempt to develop a nuclear technology in 1953 ended up in a scandal. The government had convinced three German physicists who had worked for the Nazi nuclear effort during the war, to come and resume their

work in Brazil. Three gas centrifuges for uranium enrichment were to be shipped secretly from West Germany to Brazil. But the shipment was eventually embargoed by the US High Commissioner for Germany, stopping that particular avenue of development.

Until the signing of an agreement with West Germany in 1975, Brazil had remained in the nuclear sphere of influence of the United States. During the Korean war, it delivered monazitic sands to the US Atomic Energy Commission in unlimited quantities and without compensation. Any attempts to develop a national approach on nuclear energy came into conflict with US commercial interests. In the 1960s a group of Brazilian physicists and engineers calling itself the "thorium group" was doing research in Belo Horizonte on the design of a reactor which would make use of the exceptionally abundant reserves of thorium in Brazil. Their recommendations were ignored by government and their research funds cut off after four years, as negotiations for buying a Westinghouse PWR of 626 MW were getting under way. The sale of this first nuclear plant, Angra I, was confirmed in 1972. Construction is nearing completion in Angra dos Reis on

the Atlantic coast, 130 km from Rio de Janeiro. This sale marked the high point of the influence of the United States in Brazilian energy policy.

"The present Brazilian nuclear programme is almost exclusively the result of Brazilian diplomacy and has little to do with national science and technology; those have been relegated effectively to second place, or to a marginal role" wrote Luiz Pinguelli Rosa, secretary of the Brazilian Physical Society. This sour comment reflects the government's total lack of esteem for its own scientists; their suggestion of 15 years ago to develop a thorium-fuelled reactor is now even presented in official speeches as an alternative coming from the US.

The German agreement encompasses all aspects of nuclear technology, from the prospection of fissile materials to the construction of depositories for waste. There would be a whole industry, capable of operating the complete nuclear fuel cycle. But only accessory parts are under construction so far: a fuel rods conditioning plant will be operational this year, and a heavy equipment complex, NUCLEP, for manufacturing boilers, heat exchangers and possibly turbines, is also under construction.

Two parts of the agreement raised most international concern: those for enriching uranium (breaking the American monopoly) and for construction of a fuel recycling plant, capable of extracting plutonium. In its early days, the Carter administration was anxious to stop these two plants. The diplomatic tug of war is

continuing, with the United States trying to restrict the spread of "sensitive" technologies and materials and Brazil insisting on the right to include nuclear energy in its development strategy. In the words of Brazil's chief delegate to the International Nuclear Fuel Cycle Evaluation (INFCE), Ambassador Carlos Augusto Proenca Rosa: "the use of nuclear energy in developing countries was treated by INFCE in a restrictive and limited way; there are insinuations, at times, that the major contribution that developing countries could offer in the field of nuclear energy should be to increase the prospection and extraction of their uranium resource to benefit the importing developed countries . . . We firmly believe that any effective policy of non-proliferation must be non-discriminatory and must bring about measures which are universally applicable, in order not only to guarantee the correct use of nuclear energy by countries which do not possess nuclear weapons, but also to put a stop to the arms race between countries which possess them."

The suspicions repeatedly raised about the Brazilian military government's intentions to develop a bellicose nuclear capacity rely upon past aggression towards Argentina, which led to wars in the 19th century. Today, however, both countries' harsh military regimes are much more interested in signing agreements on exchange of technology, and common ventures, than fomenting regional tensions. Numerous official visits and meetings of the heads of the nuclear programmes of each country have taken place. Each time the peaceful purpose of both countries' nuclear involvement was reaffirmed. Argentina possesses the only nuclear plant operating in Latin America — Atucha I — which functions with natural uranium. It is also negotiating with West Germany's KWU to buy a new nuclear plant similar to the ones being built in Brazil. As the Brazilian programme meets with increasing delays but the industrial capacity for nuclear components develops in both countries, the two countries have entered an era of increasing commercial cooperation, and no-one talks now of any potential enemy to use nuclear weapons against.

But even if Latin America remains free of nuclear weapons, it will not remain free of nuclear waste. To a question about where nuclear waste from the Brazilian programme would be stored, Rex Nazare, acting director of CNEN, the National Commission for Nuclear Energy, responded: "this is not yet defined. But up to six months before the first plant starts operating there is still time to define the location where to deposit waste."

Finding the sites may be difficult, because Brazilian public opinion is becoming aware of the concern that this issue has raised in developed countries. The only site proposed so far is in the mountains

behind Rio de Janeiro, a place with abundant surface water and where a large proportion of the vegetables consumed in Rio are grown. With the modest redemocratization of the military regime an amount of discussion has taken place, which has led the government to abandon the site.

The government presented its justifications for the agreement with Germany as a white paper in 1977. It claimed that nuclear power was "a necessity in view of Brazil's energy needs" and because the price of oil was increasing. It claimed that, between 1940 and 1973, the proportion of imported energy rose from 15 to 40%, and that "the hydroelectric option is approaching its natural economic limit". Paulo Nogueira Batista, director of NUCLEBRAS, the state nuclear corporation, declared that the

German view

● Many of the Brazilian nuclear opposition's calculations on hydropower are "erroneous and foolish", a spokesman for the West German federal ministry for science and technology claimed in a telephone interview last week.

There are no engineers in the opposition group, said the spokesman, and so the costs and difficulty of transporting current from distant hydro stations have been underestimated. Moreover, the Brazilian government had told Germany that by 1995 all available water resources will have been exhausted. "That's why they want to go nuclear."

The contract with Brazil allows for the supply of two reactors, Angra II and III, with options for an additional six. West German participation would decrease in the later reactors, with Brazilian participation rising to 70-90%. "But we would be happy if Brazil approves the Angra III reactor later this year." The deal was important for Germany because "if the nuclear industry wants to be economic they have to produce something", and with nuclear opposition strong in Germany deals with countries such as Brazil and Argentina were attractive. Nuclear opposition in Brazil was decreasing, the spokesman believed.

Pilot plant design for a gas nozzle enrichment plant was nearly complete, and construction has begun on site, but it will proceed at a leisurely pace. For reprocessing used fuel, Brazilian chemists and engineers are in training in Germany and working on the design of a pilot plant.

Safeguards against the diversion of nuclear materials for weapons building are included in a February 1976 agreement between the International Atomic Energy Agency and the Brazilian and West German governments. The safeguards are not "full scope", but apply only to nuclear materials and technology supplied by or derived from West Germany.

Robert Walgate

hydroelectric potential would be used up by 1990.

This technocratic argument was accompanied by reassuring declarations about the safety of nuclear energy. Technical reliability was proven from the "perfect and uninterrupted operation of close to 150 plants in 18 countries with more than 900 reactor-years of commercial service. Thus nuclear energy is the only functional alternative in view of its level of technical confidence and its competitive cost of production." The first two plants to be built with German technology (Angra II and Angra III) were promised for 1982 and 1983 respectively.

In 1974 FURNAS, the electricity supply company, had elaborated a Plan 1990 for electrical energy needs. The data presented formed the basis for the technical justifications of the agreement. It posed a growth rate of the demand for electrical energy of 11.4% per year, linked with the growth of GNP. It estimated an investment cost per plant of \$500/kW and claimed a load factor of 80% for nuclear plants, while the hydroelectric load factor in Brazil is only 50%, due to seasonal variations in rainfall.

In 1979, however, FURNAS presented a revised Plan 1992, which estimated a demand growth rate of only 7.5% a year. Considering that Plan 1990 itself had stated that "nuclear plant participation would be reduced to zero" for a growth rate below 8.7%, the revised figure becomes equivalent to proposing abandoning the whole programme. It revised the investment cost up to \$1,700/kW. The load factor of nuclear plants was brought down to 65.5% based on plants operating in the West.

During the intervening five years Brazil's "economic miracle" had come to a brutal halt: GNP grew only by 4.1% in 1977, compared to 11.8% in 1975. As censorship slackened, various sectors of the Brazilian technocracy started questioning publicly the economics of the agreement. In 1979, General Dirceu Coutinho, who headed NUCLEI, the subsidiary of NUCLEBRAS which will produce isotopes, resigned and denounced the expense of the programme.

Although criticisms of the programme had been voiced by scientists as early as 1975 at the annual meeting of SBPC, the Brazilian Society for the Progress of Science, and by the Brazilian Society for the Progress of Science, and by Brazilian scientists in exile, the defection of those locally referred to as "nucleocrats" has occurred only during the past two years. As the National Congress started functioning again, it set up a Commission of Inquiry to investigate the programme. David Simon, who had headed the Angra I project and was advisor for nuclear affairs to the president of FURNAS, resigned and collaborated with the Congressional Commission, presenting detailed testimony as a technical expert. He wrote: "apart from a reduced minority of experts — mainly to be found in the world of nucleocrats — there exists a quasi unanimity in the scientific

and technical community around a set of criticisms to be made of the nuclear agreement between Brazil and Germany . . . With the present difference in cost between nuclear and hydroelectric plants, and the availability of hydroelectric sites to the end of this century, there is no need to install nuclear plants before 1990." Indeed, Professor Jose Goldemberg, president of the Brazilian Physical Society, points out that hydroelectric reserves had been purposely underestimated by a factor of two (at 100,000 MW) by FURNAS's Plan 1990.

David Simon makes a detailed cost comparison between the Angra II and III projects and an equivalent 3,400 MW hydroelectric plant. While Angra I and II together will cost \$5,000 million, the hydroelectric plant would cost \$2,700 million. The fuel costs for the nuclear plants during their lifetime would be an additional \$4,000 million (water is free).

On the purely economic side, the agreement specifies that half the costs will be paid by Brazil in Deutschmarks, while hydroelectric technology would be almost entirely costed in Brazilian currency.

His testimony also pointed out that the jet-nozzle technique for uranium enrichment to be used in Brazil is still under development in West Germany (with half the costs for research and development borne by Brazil) and that its technical and economic viability have not been proved.

It is difficult to imagine the possibility of a reconciliation between the government representatives and the scientific community over the nuclear programme. Paulo Nogueira Batista, president of NUCLEBRAS, and Said Farhat, Minister of Information, called a joint press conference last month at which Nogueira discarded FURNAS' revised Plan 1992, because "the 7.5% growth rate demand envisaged in the plan is perilously below a reliable value", and Farhat emphasized "the Brazilian decision to follow through with the international agreements linked to the execution of the nuclear programme. Being a decision of the government, this is no more subject to either divergences or dissensions. To build the nuclear plants we shall spend US \$15 billion. For the nuclear fuel cycle, we estimate an investment of US \$2.5 billion."

On the other side, Professor Luiz Pinguelli Rosa, Secretary of the Brazilian Physical Society, told *Nature* that the scientific community today demands "democratic and public discussions of energy needs, involving various sectors of the population. We, as scientists, should not fall into the temptation to propose a progressive solution as a substitute for the technocrats' miracle. The illiterate majority of the Brazilian population must first obtain the means to evaluate what nuclear energy is. Before it really needs nuclear reactors, I hope that Brazil can reach the stage of a democracy with popular participation." □

Angra II columns . . . not enough

Trouble on the beach of rotting stone

ANGRA I is a standard PWR reactor of the type sold by Westinghouse all over the world under turn-key contract. Its construction made no use of the national manufacturing capacity: the share of local suppliers in the project was only 8%, made up of civil engineering works.

Start up is promised for next year. It uses enriched uranium provided exclusively by the US, paid for via a loan from the Industrial Development Corporation of South Africa. Used fuel will be shipped back to the US, so the electrical company which will operate Angra I will not

comment on wastes on fuel reprocessing.

The doubling of the construction time is blamed on the agreement with West Germany to build two plants (Angra II and III) on the same site. Besides the obvious dangers involved in having three nuclear plants on one beach, there were other problems. While the water table was being lowered to construct the foundations, the already existing buildings slid 10 millimeters from their position. It was decided to build an "armoured diaphragm wall" around the site, 250 meters long and 17 meters deep. As work proceeded on the anchoring of foundation columns for the reactor platform, it was discovered that the ground below the beach was scattered with huge boulders which had to be pierced to reach bed-rock at a depth of 60 meters. This difficulty could have been anticipated had the engineers recalled the difficulties encountered while building the road to Angra, when a tunnel collapsed to form a huge open trench, through which the road now passes; or had they recalled that the beach's name, "Itaorna", comes from Tupi, the language most spoken in Brazil 250 years ago, meaning "rotting stone".

Setbacks also affected the construction of Angra II. Last year, the National Commission on Nuclear Energy, CNEN, which is responsible for safety, decided that the 280 columns already in the ground were not strong enough against earthquakes. As a result, the construction of the reactor base plate was halted for a year, and CNEN ordered an additional 88 columns and reinforcement of 202 of the already existing ones.

It has been pointed out that CNEN's director has always been considered pro-American, while NUCLEBRAS' is pro-German; stronger rifts could exist between them than soil vibrations.

The overall financial charges from these modifications and delays amount to \$320 million, mainly in the form of interest payments. All these costs will be borne by the electrical company FURNAS alone; it has already announced that it will raise its prices by 60% when Angra I comes on-line next year. There are clauses in the German contracts which pass the cost of technical difficulties onto the Brazilian user company; these clauses remain secret and a Sao Paulo newspaper was seized last year for publishing one of them.

The financing of the German programme is the largest loan ever obtained for a Brazilian project: it amounts to \$1,700 million, and with costs tripled from the original predictions, money is getting short. No electrical company is willing to take on the responsibility for the construction of any further plant beyond Angra III. The government and NUCLEBRAS are pressuring CESP, the utilities company of Sao Paulo, to build a fourth plant (the third of the German agreement), but CESP prefers to build more hydroelectric plants at a quarter of the cost of nuclear plants. □

CORRESPONDENCE

Swiss vote did not decide disposal issue

SIR,—In the issue of 27 March, page 294, under the heading "Power dissenters through Europe", was a report on an anti-test drilling vote in the Swiss village of Högendorf. The assertion that this vote "may have blocked effectively further nuclear development in Switzerland" is unfounded and should be corrected.

The cooperative Nagra has been charged by the Swiss government and the utilities with nuclear power plants, with working out a national disposal concept by 1985, and test drillings are an integral part of the project plans. Högendorf is one of 12 sites in north-east Switzerland for which drilling applications will soon be submitted.

Because nuclear waste disposal is recognized to be a national issue, it was clearly specified in the revised nuclear law accepted by the Swiss public in 1979 that the government is directly responsible for decisions on disposal questions. This responsibility includes any preparatory investigatory work such as the proposed test drillings.

The vote in Högendorf was of a consultative nature. This implies that the government will take such indications of local opinion into account as far as possible, but must also consider the broader, national issues involved. While the applications are being considered project work on waste disposal is continuing on a broad front including planning of further drilling in geological formations other than the deep crystalline rocks currently being investigated.

UK science budget: now the bad news

SIR,—Your report (3 April, page 391) that the science budget will be relatively stable for the next four years misses one important point. Less than half the funds of the Agricultural Research Council comes from the science budget; the majority comes from the Ministry of Agriculture, Fisheries and Food. This has been cut for 1980/1 by an average of 6% but some research institutes will, at constant value, have lost 15% of their 1979/80 budget level by 1981/2. There is no promise of stability for this funding and our fear is that it will decrease further.

I am not out, at least on this occasion, to indulge in special pleading on behalf of agricultural research, or for research in general. It is important, however, that you and your readers are aware that for at least one of the research councils the outlook is neither as good nor as stable as you implied.

Yours faithfully,

JOHN GOODIER

Agricultural Research Council, London

Genothetically speaking

SIR,—The use of new techniques in molecular biology has allowed the fragmentation of the genome of an organism and the introduction of its pieces into adequate hosts where the entire genome can be stored for the desired use when required. This collection of genes is termed in the laboratory jargon and also in the specialized literature "a library of genes". Library is defined in several English dictionaries both British and American as "a place set apart to contain books for reading,

study or reference; a collection of books, especially one for use by the public". Therefore it seems that the expression "library of genes" is inadequate. (This fact becomes more obvious taking into account that library is specifically derived from the Latin word for book, *liber*.)

The discovery of new phenomena or the introduction of new concepts may need the introduction of new words to characterize them precisely. I feel that in the case mentioned above the creation of a new word is fully justified. I would like to propose the word *genotheque* to designate the collection of genes of an organism introduced into an appropriate host species. This short word is derived from *gene* and the greek root *θηκη* (box). This last root appears with the same meaning as that proposed in several English scientific words (perithecium, spermatheca) and in other languages in the word for library (biblioteca, bibliotheque, Bibliothek.)

If we have discoltheque, why not *genotheque*?

Ke Xue not pukka

SIR,—In his letter (3 April, page 394) Gerard Piel disputed with my statement in a recent *Nature* article that "There are no cover-to-cover translations into Chinese" of foreign scientific journals as yet, by pointing to *Ke Xue* which is the Chinese edition of *Scientific American* being circulated in China. It needs however, to be clarified that this magazine is not regarded by the Chinese as belonging to the category of primary journals, which was the object under examination in my article. Another reason why I did not mention *Ke Xue* was that its publication is a joint exercise and not a solely Chinese effort.

Wallis's biblical gesture

SIR,—In Kings Norton's obituary (20 March, page 288) of Sir Barnes Wallis, he mentions that Wallis presented his £10,000 award for his wartime dambusting bomb to a charitable foundation (to help educate the sons and daughters of men who died serving with the RAF). Why he did this deserves to be known. In the book *The Dam Busters*, Paul Brickhill relates the tremendous effort expended for the German dams' raid. When it was radioed by 617 squadron that the Mohne and Eder dams were breached, Sir Wallis was ecstatic that the huge work succeeded. Afterwards, though, he learned that 50% of the attacking planes were lost with the death of 53 very young men. He was shocked and saddened, and said "Oh, if I'd only known, I'd never have started this!" Many years later he was presented the above award. When Paul Brickhill asked him why he gave it away, he replied: "My dear chap, go and read your Bible, turn up Samuel II, Chapter 23. You probably haven't a Bible, so I'll tell you this story about David.

"He was hiding in the cave of Adullam after the Philistines had seized Bethlehem, and in his anguish he said, 'O that one would give me a drink of water of the well of Bethlehem, which is by the gate!' Now the three mighty men who were his lieutenants were with him, and I'm dashed if they didn't fight their way through the Philistine lines and draw a goatskin of water out of the well by the gate.

They fought their way back and took the water to David in the cave, but when they told him how they had got it, he would not drink it. They asked him why, and he said: 'Is not this the blood of the men that went in jeopardy of their lives?'"

Optical effects in taxis

SIR,—I wonder if any of your readers can explain a strange optical perception effect I've noticed when travelling in a London taxi-cab? No-one I've described it to has a simple explanation; and I assure you it is not restricted to trips taken after alcoholic lunches. The effect is most visible at night.

London taxis, like many others, have a vertical glass partition between the passenger seats, which face forwards, and the driver. Behind the passenger is the rear window of the cab, through which can be seen the receding road, street lights, other vehicles and buildings.

The glass partition acts like a partial mirror; in it one sees a reflection of the view through the rear window, and through it the back of the driver, the meter, and part of the view through the front cab window.

The effect — and when one has spotted it it is quite marked — is that the objects reflected in the partition glass (ie those in the view through the rear window) appear to be receding very fast, much faster than the cab is apparently travelling judging by the view forward through the partition. Subjectively, the impression is of about twice the cab's real speed. I first noticed it with the reflection of traffic lights receding at night as the cab passed them.

The effect disappears completely if one turns around and looks directly out of the rear window; there one's perception is roughly as expected. Turning back to the reflection of the same view, the recession seems to speed up again.

The only explanation I can think of is that the fixed angular size of most of the through-screen images (the back of the driver, the cab) and the increasing angular size of others (the road forward) provides a reference frame against which the decreasing angular size of the reflection is correctly perceived. Turning around, the frame of the window is too peripheral to provide an effective reference, and the brain's mechanisms for maintaining a constant perception of size of an object despite its distance come into play. Is this a possibility?

Yours faithfully,

ROBERT WALGATE

NEWS AND VIEWS

Pores for thought

from Peter Newmark

MEMBRANE pores, like teeth, can be probed, filled or extracted. Each approach can be useful in the investigation of pore structure and function and each has its advocates. In time the evidence obtained by different approaches should merge but to judge by a recent meeting*, this has not happened yet.

The sodium and the potassium channels that generate action potentials in nerves continue to provoke a good deal of interest and controversy more than a quarter of a century after Hodgkin and Huxley put their electrophysiology on a mathematical basis. The Hodgkin-Huxley model proposed that each channel had a gate which was normally closed but could be opened by depolarisation of the nerve membrane. They postulated that the gates contained three charged particles, and that their successive movement in response to depolarisation allowed ions to start flowing through the channels. It was predicted that their movement should generate a detectable gating current preceding — and much smaller than — the ionic current. The detection of gating currents became a reality in 1972 when both C. Armstrong and R. Keynes recorded them from the sodium channel of the squid giant axon. Keynes (University of Cambridge) now believes that his original conclusion that the gating currents associated with the activation of sodium channels fitted the Hodgkin-Huxley three particle model is wrong. He now gives a mathematical description of the time course of the changes in gating current in terms of two exponential functions and a single constant. This equation is not compatible with the three particle model but nor does it lend itself to any other obvious physical model. Armstrong (University of Pennsylvania) meanwhile obtains what appear to be somewhat different gating currents from the same preparation and describes them with a far more complex equation than that of Keynes. But, like Keynes, Armstrong concludes that the simple Hodgkin-Huxley model is an inadequate physical explanation of gating currents. His tentative model is considerably more complex and also

without an obvious physical counterpart.

The problem of finding physical counterparts to electrophysiological data is that of how to relate an alteration in electric field to a movement of the gating particles — in biochemical terms a conformational change — which brings about the opening of an ion channel. Also to be explained is how, for example, a low pH acting from the inside, and only from the inside, of frog muscle almost completely prevents the closing of sodium channels without having any effect on their opening and the peak sodium flow through them. (W. Nonner, University of Washington, Seattle — see *Nature* **284**, 360; 1980).

Biochemists, at least, believe that all will be revealed once they have purified the protein that encompasses the channel in question. For that reason Y. Ovchinnikov (Shemyakin Institute, Moscow) set a considerable workforce to the task of purifying the sodium channel protein from the nerve in the muscle of the walking legs of 35,000 crabs. The protein thereby isolated has an overall molecular weight of about 250,000 and consists of four subunits of which a 76,000 molecular weight component associated with a 56,000 molecular weight component is the target for a photoaffinity labelled scorpion toxin. However, W. Catterall (University of Washington, Seattle) has a different photoaffinity-labelled scorpion toxin which picks out a much larger protein (250,000 molecular weight) from either neuroblastoma cells or rat brain synaptosomes together with a 32,000 molecular weight protein from the latter. These proteins are shown to be associated with the sodium channel both because mutant neuroblastoma cells that lack sodium channels also lack the 250,000 molecular weight protein and because either depolarisation or unlabelled toxin are capable of blocking the photoaffinity labelling of synaptosomes. (*Proc. natn. Acad. Sci. U.S.A.* **77**, 639; 1979).

The biochemistry of calcium ATPase is far more advanced. Of its 1000 amino acid residues 830 are already known (N. M. Green, National Institute for Medical Research, Mill Hill) and from that and other evidence it is possible to infer how the protein is threaded in and out of the sarcoplasmic reticulum membrane in which it sits. Perhaps with the complete

sequence it will be possible to see whether the calcium channel is formed between dimers or through a monomer. Intuitively, Green favours the monomer theory as does J. Kyte (University of California, San Diego) who argued cogently for a reappraisal of the current dimer theory of channel formation for sodium, potassium ATPase.

The acetylcholine receptor is another protein of interest to both biochemists and electrophysiologists. After two molecules of acetylcholine have bound to their receptor, a water-filled pore opens allowing ions to pass through. Purification of the protein yields a major 40,000 molecular weight protein and several minor components whose roles seem to be becoming less clear. In particular J.P. Changeux (Pasteur Institute) reported that the minor component which he had previously thought to be the 'ionophore' could not be involved in ion flow because it could be removed by alkaline extraction without loss of activity.

The function of two other minor subunits is also unclear and attention is now firmly focused on the 40,000 molecular weight major subunit. Its amino acid sequence, derived either from the purified protein or from DNA, reverse transcribed from messenger RNA, should be available shortly.

Meanwhile the goal of consistently and convincingly reconstituting purified acetylcholine receptor in lipid bilayers whilst retaining ion flux and binding parameters continues to elude P. Mueller (Eastern Pennsylvania Psychiatric Institute) and many others. Changeux, however, claimed some success in reconstituting into small lipid vesicles the acetylcholine receptor of alkaline-treated, solubilized synaptic membranes of the Torpedo electric organ. The key to success, he claimed, was the addition of exogenous lipid.

One good reason for wanting purified reconstituted acetylcholine receptors is that it will enable more sophisticated electrophysiology to be carried out. But even with *in situ* receptors, great advances have been made with the advent of single channel recording. This technique, pioneered by E. Neher and B. Sakmann of the Max-Planck-Institute for Biophysical

*An International Titisee Conference on Membrane Channels held at Titisee, March 6-9 1980, sponsored by Firma Dr. Karl Thomae GmbH.

Chemistry, Goettingen has recently been applied in that Institute to desensitized channels of extra-synaptic membranes of denervated frog muscle. The desensitized form of the channels is an inactive state adopted about 10 sec after the channel has converted from closed to open form in the presence of high concentrations of acetylcholine. Sakmann reported that desensitized channels can suddenly become active again, rapidly fluctuating between open and closed states for less than a second before returning to inactivity. After a very brief delay the cycle may be repeated; after several repeats, there is a prolonged period of inactivity before bursts of activity reappear.

Neher reported the considerable technical achievement of extending single channel recording to potassium channels of the squid axon, although not under normal physiological conditions. This is the first time that the opening and closing of a single channel in a biological membrane, other than those induced by acetylcholine, has been recorded. Currents of 1.7 to 7.0 pA and a mean opening time of 12 msec were recorded. More interesting was the fact that short interruptions could be seen during the open time recording, indicating a temporarily closed condition between the closed and open states. On average there were 1.8 interruptions per open channel recording. According to Neher this refutes the Hodgkin and Huxley model which, for potassium channels,

would predict 0.4 interruptions per channel.

Single channel recording is becoming an extremely important technique for confirming and extending what has been learnt from gating currents and fluctuation analysis in the last few years. It is technically demanding particularly in terms of obtaining sufficiently good seals between the recording pipette and the tissue membrane. But there is every reason to believe that the first recordings of single sodium channels will be reported soon and will be followed by those of channels induced by a variety of neurotransmitters.

An utterly different approach to determining single channel currents, but one applicable only to the much studied model of gramicidin A channels induced in lipid bilayers, was reported by D. Urry (University of Alabama Medical Centre). By means of sodium-23 nuclear magnetic resonance he was able to demonstrate two sodium binding sites and to derive the relevant rate constants. From them and using a model based in part upon the X-ray diffraction data of Koppe *et al.* (*Nature* 279, 723; 1979) Urry then calculated a single channel current which agreed well with observed values. The validity of this approach having been proven to Urry's satisfaction, he expects soon to determine the actual positions of the binding sites within the channel. That will perhaps conclude the exhaustive studies, exhaustingly reported, of the exact way in which sodium ions make their way through the gramicidin channel. □

Climatic perturbations

from A. Henderson-Sellers

REINFORCEMENT of climatic perturbations by the natural feedback mechanisms in the atmosphere was a predominant theme of the First International School of Climatology*.

Probably the most exciting indications of internal feedback response amplifying natural climatic variations were the results presented by J. Namias (Scripps Institution) and W. Broecker (Lamont Doherty Observatory). Namias' theories are the culmination of many years of scientific investigations of synoptic meteorology. He presented examples from the USA of atmospheric reinforcement of anomalous situations in various conditions from arid to arctic. (There is an interesting analogy here with the Northern European Drought of 1975/76 which, it has since been suggested, may have persisted because of the extreme conditions of low soil moisture and high reflectivity which it had itself produced). Perhaps more important for those interested in the onset

of ice ages was Namias' further observation that baroclinic development in arctic regions seems to lead to the 'steering' of depression systems along the snow/ice boundary. This gives rise to a positive feedback mechanism in which any precipitation which occurs will 'feed' the snow advance.

The second novel case of an ecosystem response tending to enhance climatic perturbations was described by Broecker. Recent results suggest that the level of carbon dioxide in the Earth's atmosphere was considerably lower (~200 p.p.m.) during glacial epochs compared with the present day (320 p.p.m.). This decreased level of CO₂ would, of course, tend to lower average surface temperatures by decreasing the 'greenhouse effect'. However, the lowered CO₂ level may itself be a result of the onset of continental glaciations. Broecker believes that when sea levels fell as the ice mass on the

Northern Hemisphere continents increased there may have been a sudden input of phosphorus to the oceans due to leaching from the then dry continental shelves. The increased phosphorus levels would stimulate increased photosynthetic activity in the oceanic biomass and thus lead to lowered levels of CO₂ in the atmosphere. This mechanism provides a link between Northern Hemisphere glaciations and Southern Hemisphere temperatures and also indicates the importance of internal responses within the biosphere and hydrosphere for the enhancement of climatic anomalies. It does not, however, explain the origin of the decreased temperatures that triggered the original continental glaciations.

The extreme importance for climatic change of the oceans and particularly the biomass within them was re-emphasized by J. Woods (Southampton) and B. Bolin (Stockholm). Woods presented new and exciting data which indicate that there is a large-scale, but previously neglected, interchange of both water and heat between the major world oceans. Bolin's work on the carbon dioxide budget also underlines the desperate need for a fuller investigation of the oceanic contribution to global sources and sinks of CO₂. Bolin and J. Smagorinski (Princeton) both noted a 4-year fluctuation in the observed levels of atmospheric CO₂ which becomes apparent when the annual oscillation forced by industrial output and biospheric uptake is removed. There is a strong possibility that the atmospheric CO₂ levels are responding to increased uptake by the oceanic biomass during periods of enhanced upwelling. This is another link between atmosphere, climate, sea surface temperatures and the biosphere. One is tempted to reconsider these complex interrelationships in the light of Lovelock's 'Gaia Hypothesis' (Oxford University Press, 1979).

In view of the extremely complex nature of the response of the biosphere to climatic changes it was reassuring to hear from H. Fritts (Arizona) that, given a large enough sample size, biological data (especially from tree rings) could be shown to provide satisfactory reconstructions of past climates. The elegance and strength of the mathematical techniques used in this type of reconstruction (which now allows Fritts to draw surface pressure charts for earlier epochs) may lead to biological data superseding the traditional historical data sources for climatic reconstructions. Although the response of trees to climatic variation may be complex, the signal is, at least, not further confused by intentional modification of the true situation (as is known to have occurred in certain mediaeval manorial reports of crop yields written for absent landlords). Climatic reconstruction and monitoring thus cannot be successfully developed without detailed consideration of both anthropogenic and environmental systems with which the atmosphere is intimately linked. □

*A NATO Advanced Study Institute, held at Erice, Sicily on 9-21 March, 1980. The proceedings will be published by Reidel.

A. Henderson-Sellers is in the Department of Geography, University of Liverpool.

ON the premise that the climate has changed in the past and thus may well change in the future a Government 'think tank' — the Interdepartmental Group on Climatology — was set up to 'consider whether the United Kingdom was putting sufficient effort into studying the climate'. This group, under the chairmanship of Sir Kenneth Berrill has just delivered its first report*.

The review of the present state of knowledge on climatic change (with special reference to the United Kingdom) is clear, succinct and realistic, but restricted to short-term changes. Major emphasis is given to the carbon dioxide issue (fossil fuel burning and deforestation leading to increased atmospheric carbon dioxide leading to possible global warming), and interesting estimates are given of the economic effects of a 1°C warming (a saving of £250 million per year through reduced energy demand), and the cost of a single severe winter (in excess of £80 million). This section ends with the rather optimistic statement that "within a few years sufficient progress will be made" in predicting the effects of global climatic change on the United Kingdom that climate trends will be able to be considered in future Government planning. This statement implies an understanding of the causes of natural and anthropogenic climatic change which we do not have at present, and would be viewed with scepticism in some circles.

As a review of the present state of knowledge, the Report is deficient in its neglect of studies of climatic change which are based on historical or proxy

*Climatic change. Its potential effects on the United Kingdom and the implications for research, London, Her Majesty's Stationery Office, 1980.

Climatic change

from T.M.L. Wigley

data. This is disappointing since a number of world authorities in these areas are British, and British scientists have been involved in some important recent works. For example, the verification that orbital changes have a major controlling role in determining the cycle of ice ages (Hayes *et al.*, *Science* 194, 1121; 1976) is believed by many to be the major work on climatic change this decade. It might be argued that long-term climatic change (the topic of the Hays *et al.*, paper) was not of any immediate relevance. However, analysis of the past few hundred thousand years has revealed evidence that very rapid climatic changes have occurred in the past (see, for example, Hollin *Nature* 283, 629, 1980). Such changes, if they occurred today, would undoubtedly have a dramatic impact on society. The Report's emphasis on the instrumental record and computer modelling tends to reflect the work on climatic change which is being conducted in the U.K. Meteorological Office. As such it creates an unbalanced impression of work in progress in the U.K. as a whole. This impression is reinforced by the summary of research funding. Only £1 million per year is expended directly in support of research on climatic change: divided into studies of past climates (£¼ million per year) and climate modelling (£¾ million per year). From other figures quoted in the Report, it is apparent that the bulk of this expenditure is within the Meteorological Office. But how good are these estimates and how well do they reflect the work on climatic change which

is being carried out in the United Kingdom?

If one were to consider all research into past climates which is being conducted in the United Kingdom, then the figure of £¼ million per year would be an underestimate. However, a significant amount of funding in this area comes from outside the U.K., and it seems that the Report has considered only U.K.-funded research. Since this restriction has not been stated, the figures tend to be misleading — and a more complete analysis would be of great interest. But how can one properly review all U.K. research into the many facets of climatic change? Funding figures can be deceptive, even if correctly assessed, since certain items of research (such as climate modelling) are extremely expensive. How many scientists are working in the area, how much material is published, and how are these figures distributed amongst the various government bodies, the universities and private industry? These are important questions which the Group has not yet considered.

It is a pity that this Report is restricted to a review of research within, or funded by, the Government. By so doing, a considerable amount of research which is important in the study of climatic change has been neglected. Unfortunately, except in the title no statement is made of the restricted nature of the Report, and, because of this, it can only be misleading to the uninitiated. The Interdepartmental Group on Climatology has, however, not been disbanded, and we can, perhaps, look forward to a more comprehensive review at a later stage. □

T.M.L. Wigley is in the Climatic Research Unit, University of East Anglia.

Sign language and spoken language

from James E. Cutting

WHAT is the nature of language? This question has taken on new vitality with our increasing recognition of a whole family of languages previously ignored by linguists, philosophers, psychologists, and neurologists. These languages are the sign languages of the world used by communities of the deaf in enclaves scattered about the globe. These languages are, we suspect, as varied and different as are spoken languages; they are, we now recognize, not at all parasitic on the spoken languages around them; and they have been, regrettably, little studied so far.

How do sign languages differ from spoken languages? How are they similar? What is characteristic of language in general, encompassing both signed and spoken languages? These were among some of the fundamental questions which were discussed at a recent conference*.

By comparison with spoken languages, little is known about sign languages and the only substantial study to date is that of Klima and Bellugi (*The signs of language* Harvard Univ. Press, 1979) on American sign language (ASL). Cross-linguistic study with Chinese Sign Language, French Sign Language (FSL), British Sign Language (BSL), and others has only just begun. One of the interesting facts about these languages is that users of ASL find FSL much more intelligible than BSL, undoubtedly because the American and French sign languages are historically related to one another and quite independent of BSL. This is important

*A Dahlem workshop on Sign Language and Spoken Language, held in Berlin 24-28 March 1980, under the auspices of Senat der Stadt Berlin and Stifterverband für die Deutsche Wissenschaft. The proceedings will be published later this year by Dahlem Konferenzen, edited by U. Bellugi and M. Studdert-Kennedy.

evidence for the independence of the signed from the spoken languages that surround them.

At first glance one might suspect that sign and speech are quite different, if for no other reason than we have two hands for articulation but only one tongue. Interestingly, however, in sign language bilateral gestures in which either opposition or symmetry between movements of the two arms is used seem to be rare. Historical analysis suggests that the evolution of signs may be in the direction of simple one-handed forms.

We can consider sign to entail the shape and movement of the dominant hand (signers can be right- or left-handed) from one place of articulation to another with coordinate gestures of the head and shoulders — just as speech may be thought of as movement of the tongue from one place of articulation to another with co-ordinate closures and releases of the lips and larynx. The places of articulation for signs are centered in two distinct areas. One is

100 years ago

Seeing by Electricity

It may be well to intimate that complete means for seeing by telegraphy have been known for some time by scientific men. The following plan was suggested to us some three years ago by a picture in *Punch*. Our transmitter at A consisted of a large square made up of very small separate squares of selenium. One end of each piece was connected by an insulated wire with the distant place, B, and the other end of each piece connected with the ground. The object whose image was to be sent by telegraph was illuminated very strongly, and, by means of a lens, a very large image thrown on the surface of the transmitter. Now it is well known that if each little piece

of selenium forms part of a circuit in which there is a constant electromotive force the current passing through each piece will depend on its illumination. Hence the strength of electric current in each telegraph line would depend on the illumination of its extremity. Our receiver at the distant place, B, was, in our original plan, a collection of magnetic needles, the position of each of which was controlled by the electric current passing through the particular telegraph wire with which it was connected. Each magnet, by its movement, closed or opened an aperture through which light passed to illuminate the back of a small square of frosted glass. There were, of course, as many of these illuminated squares at B as of selenium squares at A, and it is quite evident that since the illumination of each square depends on the strength of the current in its circuit, and this current depends on the illumination of the selenium at the other end of the wire, the image of a distant object would in this way be transmitted as a mosaic by electricity.

From *Nature* 21 April 22, 589; 1880

around the face, generally centred between the eyebrows and mouth and off-center to the cheek ipsilateral with the dominant hand and the other is in front of the signer with the nondominant hand often used as an articulator surface for the dominant hand to play against. The coordinate gestures of the head and shoulders, however, play a different part in sign from the part played by lips and larynx in speech. Head and shoulder movement seems to serve, in part, grammatical purposes, such as denoting relative clauses, and they play no role at a sublexical level. The lips, on the other hand, play no grammatical role in any known spoken language, but are intimately involved in sublexical units.

Lexical items in speech are composed of phonemes. English has about 50. Lexical items in sign are composed of formational parameters — handshape, place of articulation, movement, and orientation — that yield somewhat more than 50 cheremes (Stokoe et al, *A dictionary of American Sign Language on linguistic principles*, Gallaudet College Press, Washington, 1965). These parameters have a somewhat different status in sign than phonemes, or even syllables, in speech; yet slips of the hand are often parameter-based just as slips of the tongue are often based on phonemic and syllabic structure. Virtually all hand configurations can go with any movement, with virtually any place of articulation, yielding as many as 10,000 possible ASL signs.

The interesting point is that these parameters are arrayed simultaneously, whereas the phonemes and syllables of speech are strewn out in time. It may be that the difference in modality has encouraged differences in manner of composition of linguistic units. Visual display may allow a more simultaneous

arrangement, and auditory display a more sequential one. Sign languages, particularly ASL, appear to use this simultaneous, spatial character in many ways.

For example, morphological functions can be overlaid on lexical items without necessarily increasing the amount of time taken to produce the sign. This is done by modulating the movement parameter of the sign such that both the original movement and the modulation can be seen. Consider the ASL sign for BLACK, articulated in citation form with the forefinger of the dominant hand extended as the hand sweeps across the eyebrows from the contralateral to ipsilateral side of the face. To change this to VERY BLACK the sweep is made with an accelerated beginning; to change it to BECOME BLACK the sweep is made with an initial tenseness or hesitation; to change it to HABITUALLY BLACK it is made repeatedly; and so forth. In this manner the lexicon of the language is syntactically enriched through the use of morphological additions quite unlike those used in English. Moreover, these operations are performed on the base sign in an essentially simultaneous layering. Spoken languages seem to be rather impoverished in terms of this kind of layering; the best candidates seem to be the vowel harmonies of languages like Finnish, the insertion of different vowels into consonant groups according to grammatical function in Hebrew, and the use of tone for grammatical purpose in certain dialects of Chinese.

A second example of the use of space by sign that has simultaneous character may be found in anaphora and pronominal reference. In sign discourse, the signer "lays out" in space for the sign recipient the actors and objects that are referred to. This is done laterally, left to right or vice versa, indicating a single place for each person or object to occupy, using as many

as four, five, or more locations. These locations are set up as they occur in discourse, and both signer and sign recipient remember their places. In this manner, pronouns analogous to *she* or *it* are actually locations in front of the signer, set up arbitrarily in discourse and held there simultaneously as long as is convenient, and removed when necessary. Spoken languages seem to have no analogue to this, partly because acoustic space may not allow tone heights to be used pronominally. It would simply be clumsy and confusing.

Thus, simultaneous layering of linguistic units and simultaneous display of anaphoric relations may be ways in which sign languages have been encouraged by modality to structure themselves. Yet simultaneity of display in vision may have costs in sequentiality. Consider proposition rates. Semanticists have used the notion of a proposition as a unit of discourse. For example, *John is a secretary* is a sentence with one proposition, and *John is a tall secretary* is a sentence with two, roughly corresponding to *John is a secretary* and *The secretary is tall*. There are many schemes for counting propositions, and semanticists have long debated which way is the best, but regardless of the scheme, sign languages (at least ASL) seem to convey only about two thirds of the propositions per unit time that spoken languages do. Thus, it may be that the visual modality encourages simultaneous layering precisely because it is constrained sequentially.

Sign languages force a broadening of our notions of what language is. Indeed, we are often surprised by what we find in sign. Surely more surprises are in store. For example, we currently have little idea of what difference there may be between apraxia and aphasia of the deaf who have suffered cerebral impairment. Yet these are useful diagnostic categories for the hearing in clinical settings. In addition, we have no real idea why second-generation signers are better than first-generation signers — that is, their language is richer — when in fact the second-generation users learned their language, by and large, from first-generation users. Answers to these and other questions will come. What will also come with increasing inquiry into sign, and this is surely the best byproduct of all, is an increasing recognition and liberation of the deaf. Traditionally, deaf peoples have had to learn in oralist mode, one particularly ill-suited to their handicap. At best they have been tutored using a language form still far removed from native sign. In the United States this form is called Signed English, which takes the lexical items of ASL and strings them together according to English syntax. Even in this situation deaf signers have been overtly discouraged from using their native language. Increasing inquiry into the sign languages of the world by deaf and hearing researchers can only help the deaf to realize their full potential. □

How long is the charmed lifetime?

from Graham Shaw

By remarkable techniques akin to the systematic location of needles in haystacks, experimental physicists have made considerable progress towards determining the lifetimes of charmed particles. In so doing, they have confirmed yet another fundamental feature of the unified theory of weak and electromagnetic interactions (see *Nature*, 282, 131; 1979).

According to theory, the lightest charmed particles should decay by weak interactions, since charm itself is conserved by the more powerful strong and electromagnetic interactions. And these weak interactions should be the same as those responsible for familiar processes like muon decay, or nuclear beta decay, with precisely the same coupling constant. However, because the charmed quarks are so much heavier than the strange quarks to which they decay, the density of allowed final states available (the 'phase space') is much greater in charm decays than in, for example, muon decays, so that the predicted lifetimes are much shorter. How much shorter depends on the charmed quark mass, but with reasonable values, lifetimes τ in the range 10^{-12} to 10^{-14} s are obtained, compared to 2.10^{-6} s for the muon lifetime.

Turning to experiment, such short lifetimes $\tau \sim 10^{-13}$ s present a serious challenge, since in a typical charm production experiment they imply decay lengths of a few hundred microns. This distance is of the same order as the bubble size in a typical bubble chamber, so that the resolu-

tion required is on the edge of what may be achieved with this technique. Very much better spatial resolution can be obtained by observing charmed particle production and decay in photographic emulsion stacks. In this case, the problem is not to resolve the details of a given event, but to find it. The events are relatively rare, and in general occur deep in the stack, so that it would take innumerable man years of effort to locate them in sufficient numbers to be interesting. A method is required to locate the needles in the haystack, without sifting every straw. This is provided in a series of so-called hybrid experiments by placing an array of electronic counters and/or a bubble chamber behind the stack (see *Nature* 279, 287; 1979). These can be used to detect the particles produced together with the charmed particle, and the decay products of the said particle, when they emerge from the stack. They serve a triple purpose: to select out possible charmed particle events from more numerous backgrounds; to identify and measure the momenta of the emerging particles; and by tracing back the flight paths of the particle into the stack, to locate the small region in which the event occurred.

An example of an event located in this way is shown in the figure, with best fit lines drawn through the measured positions of grains in the emulsion (Adamovich *et al.*, *Phys. Letters* 89B, 427; 1980). In this experiment, an 80 GeV tagged photon beam is incident from the left, and the event clearly indicates a neutral particle being produced at the first vertex, and decaying at the second. Information from the external counters indicates $\pi^+\pi^-\pi^-K^+$ as

the most likely identification for the decay products 1d, 2d, 3d, 4d, and leads to a mass for the decaying particle of 1866 ± 8 MeV/c², coincident with the mass of a charmed \bar{D}^0 meson. On the basis of this and other detailed considerations, the authors conclude that the production and decay of a \bar{D}^0 meson has almost certainly been observed. The distance between the production and decay vertices is measured in the emulsion as $122.7 \pm 2.2 \mu\text{m}$, with a corresponding decay time of $(2.26 \pm 0.05) \cdot 10^{-14}$ s.

Similar events have also been seen in several other hybrid experiments (see Voydovic, *Proceedings of the International Symposium on Lepton and Photon Interactions at High Energies*, Fermilab, Batavia, in press). In particular, a group working at Fermilab with a neutrino beam, has reported as many as ten events in which the decaying charmed particle can be identified (Prentice, *ibid.*). These include two Λ_c baryon decays with a mean decay time of about $4 \cdot 10^{-13}$ s, four D^\pm or F^\pm meson decays with a mean decay time just under 10^{-12} s, and four D^0 meson with an appreciably shorter mean decay time of about $7 \cdot 10^{-14}$ s.

These experiments, and others like them (Voydovic, *ibid.*) clearly show that charmed lifetimes lie in the expected range, providing further striking evidence for the universal coupling of the weak interactions. They also begin to reveal more detailed features, like the relative shortness of the D^0 lifetime, which has aroused considerable theoretical interest (see Rosen, *Phys. Rev. Letters* 44, 4; 1980; Bander *et al.*, *ibid.* 44, 7; 1980). Hopefully, this is only the beginning. □

Dendrochronology

from Sara Champion

CURRENT European research in dendrochronology is extending the possibility of accurate dating back into the 1st millennium B.C., and in doing so is confirming observations which could previously only have been made by the conventional method of artefact cross-dating.

When Bruno Huber, the founder of European dendrochronology, died in 1969, his master chronology for Central European oak stretched back from the present for over 1000 years (Huber, *Handbuch der Mikroskopie in der Technik* 5, 171; 1970). He had shown that the considerable variations in the ring widths of coniferous trees in North America caused by extreme temperatures, which allowed the crossmatching of skeleton plots, did not occur in the tree population in the more temperate European climate, rendering this method of crossmatching inapplicable. Concentrating on oak, the

most commonly used building timber and one suitable for interregional study, he developed the use of the agreement percentage and the fractional disagreement percentage for the evaluation of similarity of different plots. His use of the semi-logarithmic scale making the curves independent of the magnitude of absolute growth facilitated the visual comparison of different sequences. His emphasis on the recognition of *indicators* and *signatures* resulted in the establishment of several important ones: the peak in A.D. 1421, the minima in A.D. 1311, 1320 and 1326, and in particular the A.D. 1530-1540 'saw', a sequence of five alternate rises and falls which has been matched in Hollstein's West German oak chronology and has been recognised even in Becker's silver fir sequence.

Recent work has concentrated on improving the procedure for the synchronisation of individual curves, (Eckstein & Bauch *Fortwissenschaftliche Centralblatt* 88, 230; 1969; Baillie & Pilcher *Tree Ring Bulletin* 33, 7; 1973) and on extending the existing chronologies both geographically and temporally.

Chronological sequences have been constructed using the widths of the rings as a basis of comparison. For periods where sequencing of growth rings yield inadequate information for cross-matching, it has been suggested that the density of the wood or the dimensions of the cells may more clearly differentiate the years. The use of X-ray densitometry for establishing the proportion of low and high density wood (Fletcher and Hughes, *Bull. of the Fac. of Forestry*, Univ. of British Columbia 7, 41; 1970; Hughes and Sardinha, *J. Microsc.* 104/1, 91; 1975), has particular significance for dendroclimatology, since it yields detailed information on climatic conditions, but also serves to distinguish individual growth rings more clearly than simple ring width. Density is affected, however, not only by climate, but also by soil type, position of the sample in the tree, and by species so much further research is required if density is to be used alongside ring width for establishing chronologies. Variations in the dimensions of wood cells from year to year also yield detailed climatological information, and may in the future be suitable for use in constructing chronologies.

The identification of a felling year is straightforward if the sample still retains all the sapwood and bark, but research is showing that the approximate felling year can be calculated if the transition between heartwood and sapwood is present, even if most of the latter has been removed because it rots more quickly. Researchers have produced different estimates however, for the number of years to be

allowed between transition and final ring. Recent work on the timespan between felling and construction, based on the examination of timbers for drying fissures, has shown that generally wood used in buildings, bridges and other structures was not seasoned before use (as opposed to wood for cabinet-making, panels etc.), and that construction year can be assumed to be within a year of felling, apart from obvious cases of re-used old timber.

Many centres in Europe have concentrated on constructing regional chronologies, and on extending them back into early history and prehistory. Hollstein's work at Trier (summarised in *Brit. Arch. Reports* 551, 33; 1978) has aimed at establishing a chronology valid for West Germany, Luxembourg and parts of France and Switzerland. This master sequence is closely comparable to Huber's sequence (the 1530-1540 'saw' has been recognised in over 100 cases), but stretches back to A.D. 822 without serious problems. Although there are gaps in the 8th and 4th centuries A.D., use of historical dates such as the construction of the bridge over the Rhine at Cologne in A.D. 310 has allowed Hollstein to extend his chronology back to the 8th century B.C. Differences in elevation, soil and climate between Central and Western Germany and the North German lowlands have necessitated the construction of local sequences, many of which run from the 10th century A.D. to the present. Two chronologies for Sweden extend back to the 6th and 9th centuries A.D., one for Denmark to the 14th (with an earlier section 694-1191), and one for Schleswig-Holstein to the 5th century A.D.

In the Netherlands Bauch (*Brit. Arch. Reports* 551, 133; 1978) and others have established two non-matching chronologies for oak. Their chronology I (continuous back to 1385 A.D., earlier section 1036-1325 A.D.) can be synchronised with the Hollstein and Huber sequences, but their chronology II (1109-1637±1 A.D.), derived from panel paintings and sculptures executed in the Amsterdam and Leiden regions, bears little relation to these mainland European sequences. It has recently been matched, however, with the Type A chronology established for South-East England, with a high agreement percentage for the period 1354-1588 A.D. The import of timber from England is unlikely and there are, anyway, differences in the quality of the panels so the similarities in the curves have been attributed to like patterns of slow growth. A problem remains in that no examples of the Netherlands chronology II curves have been found apart from the panels; it is suggested therefore that the timber came from a source completely exhausted by 1650, the date from which Dutch panels always show the ring pattern of chronology I.

In England, the two main types of chronology identified, A and H, can be

related to continental sequences. Type A, found in South-East England and Yorkshire, has strong similarities to the Netherlands chronology II, while Type H, found in the West and on higher ground, can be correlated with the Huber and Hollstein sequences. Fletcher (*Brit. Arch. Reports* 551, 154; 1978) suggests that there may be a connection between the two chronology types and the two species of oak, sessile and pedunculate, and their preferred environment; current research on species identification should illuminate this problem.

Species other than oak are under investigation. The silver fir has been shown not only to share signatures with oak (the 1530-1540 'saw', for example), but also to be uniform in its growth pattern over a large area from Czechoslovakia to the Vosges. Hollstein's extension of the secure 1100-year fir chronology back to the 7th century B.C. through finds at the Magdalenenberg, a tumulus in the Black Forest, has enhanced the potential of this species. A chronology for beech runs back to the 14th century A.D. in Germany; research continues on the more problematical series for spruce, pine, ash and larch.

The significance of this work for archaeology is crucial. More than 300 dated samples from the important Viking trading centre at Haithabu, Schleswig (Eckstein and Liese, *Germania* 49, 155; 1971) have allowed a detailed constructional history of the site to be made: building dates for houses, wells and pavements span a period of 118 years, and evidence for sequence of structures and re-use of timbers has been produced which would have been unobtainable stratigraphically.

Uncertainties over the correct calibration of radiocarbon dates and variability in measurement have resulted in an extreme reluctance to use this dating technique in Europe for sites of the 1st millennium B.C. Dendrochronology is now producing absolute dates for sites previously dated by relative methods. Excavations at the Magdalenenberg produced timber from the primary and several secondary graves. Hollstein dated the primary grave to 577 B.C., and the secondaries to between that date and 550 B.C.; on archaeological grounds the graves would have been dated to 600-550 B.C. A rich grave at Altrier, Luxemburg, dated archaeologically to 475-400 B.C., produced a *terminus post quem* of 473 B.C. for a piece of timber with no heartwood/sapwood transition present, and a felling date of 461 B.C. for a piece of charcoal found with the cremation.

These dendrochronological dates have confirmed those suggested on archaeological grounds; once the many floating chronologies for material of the 2nd, 3rd and 4th millennia B.C., currently 'dated' by radiocarbon, are fitted to the master curves, the earlier phases of European prehistory may become dateable in calendar years, causing perhaps some upsets to established archaeological sequences. □

SPRING BOOKS SUPPLEMENT

This above all...

G.S. Stent

THIS is the second of a series of books commissioned by the Alfred P. Sloan Foundation in which according to its President "a representative selection of accomplished and articulate scientists [are] to set down their own accounts of their lives in science", in order to further the public understanding of science. Who could be more fitting for such a commission than Sir Peter Medawar, supreme among contemporary scientists for his combination of scientific excellence, erudition and literary skill? But rather than simply composing another scientific autobiography, Medawar has "tried to write the kind of book I myself should have liked to have read when I began research before most of my readers were born": a young scientist's vade-mecum that offers succour and savvy to the innocent, as provided by an experienced, wise old owl. The scope of Medawar's advice is indicated by the titles of his 12 brief chapters: "How can I tell if I am cut out to be a scientific research worker?"; "What shall I do research on?"; "How can I equip myself to be a scientist or a better one?"; "Sexism and racism in science"; "Aspects of scientific life and manners"; "Of younger and older scientists"; "Presentations"; "Experiment and discovery"; "Prizes and rewards"; "The scientific process"; and "Scientific meliorism versus scientific messianism".

There is certainly a great need for a book from which young persons interested in a scientific career but lacking direct access to senior scientists can get some authentic ideas of what it's really like to be in the business. In fact, why hasn't it been done before? And Medawar, who as an adviser to the young sees himself as the Polonius, the Lord Chesterfield or the William Cobbett of science, goes some considerable way towards filling that need. Above all, Medawar emerges from these pages as a role model worth emulating for any aspiring youth: urbane, sensible, open-

Advice to a Young Scientist. By P.B. Medawar. Pp.109. (Harper and Row: New York and London, 1980.) \$8.95, £4.95.

Sir Peter Medawar when a graduate student at Oxford, 1936.

Ramsey and Muspratt, Oxford.

minded and liberal (but, of course, intolerant of nonsense), universally esteemed, and, most importantly, outstandingly successful, having reached the absolute pinnacle of his profession with perfect grace, never clawing his way to the top. Moreover, Medawar provides many *aperçus* of the scientific life, such as that "no working scientist ever thinks of himself as old, and so long as health, rules of retirement, and fortune allow him to continue with research, he enjoys the young scientist's privilege of feeling himself born anew every morning"; that "luck plays a real part in scientific research"; and that "the husband of a [woman] scientist must not expect to find *gigot de poulette cuit à la vapeur de Marjolaine* ready on the table when he gets

home from work probably less taxing than his wife's".

But I do not think the book completely achieves its aims. First, the down-to-earth questions posed in some of the chapter titles are not all given very helpful answers. Thus if the young reader really wants to know if he is cut out to be a scientific research worker, he is provided with little more on which to base his decision than the information that science (just like, say, professional skiing) is a very demanding and sometimes exhausting, albeit exciting and rather passionate, occupation, for which old-fashioned virtues such as diligence, a sense of purpose, and the power to concentrate and persevere are required. Moreover, he should be able to pass an intelligence test provided by Medawar, which consists of discovering what is wrong with the theory that El Greco painted unnaturally tall and thin human figures because of a defect in the painter's vision that made him see people that way. And if the young reader really wants to know what he should do research on, he is given little more guidance than the aphorism that he "who wants to make important discoveries must study important problems". By way of an example of an unimportant piece of research *not* worth doing, Medawar mentions the case of a young zoology graduate student who decided to find out why 36% of sea urchin eggs have a tiny black spot on them. It so happens that I myself am very interested in the role of topographic differentiation of the egg in embryonic development and became very excited on learning that there are black spots on a substantial minority of sea urchin eggs. In fact, I had already worked out the beginnings of a black spot theory of development before I came to the dénouement when Medawar reveals that there are no such black spots and that it was all made up by Lord Zuckerman. And if the young reader wants to know how to equip

himself to be a scientist, he is informed only that he must read the literature (but not too much), that he better get some results (even if they are not original), that he should not waste time building equipment (if it can be store-bought), and, above all, that he ought to practise what Medawar in an earlier book called "The Art of the Soluble" (which is "making a problem soluble by finding out ways of getting at it — soft underbellies and the like").

A second shortcoming of the book likely to trouble intellectually alert young readers is a noticeable lack of logical consistency in some of the propositions put forward by Medawar. For instance, he cautions against "citing Marie Curie as evidence that women can do well in science; any such tendency to generalize from isolated instances will convince no one that they have a natural aptitude for science — it is not Madame Curie but tens of thousands of women gainfully and often happily engaged in scientific pursuits who should be called in evidence". Yet in the same chapter, Medawar merely cites the names of ten brilliant contemporary Hungarians (most of Jewish descent) to demolish the inference drawn from IQ tests administered at Ellis Island before the First World War "that 83 percent of the Jews and 80 percent of the Hungarians seeking entry were feeble-minded". Rather than generalizing from isolated instances, should Medawar not have called into evidence the tens of thousands of Hungarian and Jewish immigrants who did just about as well in the New World as their Anglo-Saxon fellow-citizens? Further, in one place Medawar indignantly rejects the notion that there are any national differences in the character of science — he mentions Japan in particular as one nation whose science has been falsely held to be somehow different from that of the West. In fact, he thinks that such "regional differences are intrinsically unlikely for methodological reasons" and asserts "that no experienced scientist seriously believes that they exist", thus sweeping away with a few strokes of the pen all of Joseph Needham's studies of Chinese science that show that culture *has* a profound influence on the way science is done. Yet a few pages later he makes fun of Fernand Braudel's dictum that history devours the present by calling it (with undoubted chauvinist irony) one of "those profound French epigrams, you know". In another place Medawar declares that "most of the very greatest scientists lived long before Alfred Nobel . . . founded the prize". But some pages later he declares that science has no limits and "will dry up only if scientists lose or fail to exercise the power or incentive to imagine what the truth might be". So, since the vast majority of scientists that ever lived have lived in this century and since their labours have presumably carried us far away from nineteenth century science into the limitless sea of scientific knowledge, the keen young reader will

Sir Peter Medawar

MRC Publications Group

wonder how it is possible that most of the "greatest" scientists happened to have been among that tiny band of old-timers. Is Medawar not giving himself over to what he castigates at the very end of his book as "Arcadian thinking [which] looks not forward nor far away but backward to a golden age that could yet return"?

In this connection it is instructive to examine Medawar's statement that "one can envisage an end of science no more readily than one can envisage an end of imaginative literature or the fine arts". Interpreted literally this statement would merely assert that it is just as easy to envisage an end of literature and the arts as it is to envisage an end to science. But in the context in which it appears in this book the intended meaning of the statement is undoubtedly the claim that it is very difficult to envisage an end to either of these activities. But this claim would be counterfactual since it is, in fact, easy to envisage an end of the sciences and the arts, as was done, for instance, by Hermann Hesse in his *Glass Bead Game*. And it is precisely from envisaging an end of imaginative literature and the fine arts in

our time that the view that most of the very greatest artists lived before our time gains its logical justification.

But these niggling criticisms are not meant to imply that *Advice to a Young Scientist* cannot be read with great profit by young and old alike. On the contrary, the impression that I want to leave is that this book is bound to enlarge any reader's intellectual horizon and give him a good grasp of what it is like to devote one's life to what Medawar calls "exploratory activities of which the purpose is to come to a better understanding of the natural world". For such a life a critical mind is required, which Medawar challenges with the following "chestnut of immemorial origin":

Psychiatrist: Why do you flail your arms around like that?

Patient: To keep the wild elephants at bay.

Psychiatrist: But there aren't any wild elephants here.

Patient: That's right. Effective, isn't it?

Re-opening the case for natural theology

Stanley L. Jaki

Creation and the World of Science: The Bampton Lectures, 1978. By A. R. Peacocke. (Clarendon/Oxford University Press: Oxford, 1979.) £10.

A THAW has been developing for the past decade or so in the icy truce between science and Christian religion. Such is the first thesis of the Reverend Dr A. R. Peacocke, Dean of Clare College, Cambridge, in this book, the greatly expanded form of the Bampton Lectures for 1978. Of course, there were some tell-tale events well antedating the 1970s. It was a quarter of a century ago that Julian Huxley chose to drop from the second edition of his *Religion without Revelation* a crusading preface, his clarion call to all men to rid themselves, once and for all, of the illusion of being dependent on a personal God. Such a call is almost invariably orchestrated in that major key which is the presumed irreconcilability of science and religion and which is aimed primarily at the Christian creed, the major form of belief in God in the Western world, the cradle and powerhouse of science.

As to the past decade, it has widely witnessed the survival value of religion without revelation, after the late Jacob Bronowski refused to heed a suggestion of BBC Television to let them produce his *Ascent of Man* without its anti-Christian innuendos. Religion without revelation could, if the second Bronowski-lecturer (Philip Morrison) was right, be developed by termites, who, given enough time, perhaps billions of years, would come up, so he claimed, with a telescope worthy of Palomar. Like-minded pundits are no longer the exclusive voice of the world of science. Indeed, not since the days of a 'holy wedlock' between science and Christian religion (the days of Boyle and Newton) has it been as fashionable for scientists to refer to creation as is the case nowadays. Peacocke avoids following them into taking the 2.7°K cosmic background radiation for a measuring device of time elapsed since the moment of creation. At any rate, cosmology (the basic science, if all science is cosmology — a proposition endorsed by Popper and with no touch of falsifiability) is not among the major sources, surveyed by Peacocke, of the thaw in question. He rather emphasizes the rising awareness among scientists of the revisability and socio-psychological conditioning of their assumptions and theories. Another major source is that

ecological concern which forced the scientific community to face up to questions of ethics, often germane to a theological perspective.

Therefore the times are propitious, Peacocke argues, for re-opening the case for natural theology. Indeed, its thorough recasting is in order, if it is true, and Peacocke, a biochemist by first training, has no doubt that science has clarified all basic questions about all forms of life, including man, by showing that all are but 'living matter', so many complex agglomerates of atoms and molecules. Thus, if for the Christian theologian the world is to remain a 'launching pad' towards its Creator, the world must be perceived through lenses 'ground and polished by science' (page 48).

Peacocke does not have in mind a stance of 'genueflecting to science', a stance anyhow incompatible with the stipulations of the Reverend John Bampton, Canon of Salisbury. The Bampton-lecturer, a scholar in Anglican orders, must preach 'eight Divinity Lecture Sermons' on any of six specified topics, all of which restrict genuflection before the Triune God alone. Since the last of those topics, 'the Articles of the Christian Faith, as Comprehended in the Apostles' and Nicene Creed', rests on the dogma of the createdness of all things visible and invisible, a thorough confrontation of science and Christian faith is unavoidable, if the latter is to remain a 'reasoned service', a stipulation of the Apostle Paul. Such a confrontation is meaningful only if the merits of the respective claims of science and of (Christian) religion are subjected to a thorough scrutiny, which touches not only on the very foundations of Christian theology but also on those of science. Therefore an undertaking of this sort must be of considerable interest to those natural-scientist readers of *Nature* who cherish vistas of science extending far beyond their often extremely circumscribed specializations.

The theme of thaw and its background, which is the topic of Chapter 1, is followed by 'Cosmos, Man and Creation' in which the shift from the world picture of classical physics to that of modern physics, the interplay of chance and necessity, and the Judeo-Christian doctrine of creation are dealt with. Chance is again considered in Chapter 3, and with special attention to the ideas of Monod, Prigogine and Eigen on emergent systems. Peacocke's discussion of the mind-body relationship, the substance of Chapter 4, may have come more logically after his discussion of evolution ('The Selfish Gene and What Men Live By'). All these chapters certainly should keep alive the interest of scientists.

Chapter 5, in itself a small book, is strongly theological, which is not to say that it is uninteresting. Peacocke's treatment of man's ethical nature and of Jesus' life and resurrection will delight those who savour process theology taken in

a broader sense. Peacocke explicitly dissociates himself from neo-Thomists and Barthians. His predilection is rather with process theologians who showed marked interest in science and who published mostly during the past decade. While attention to the latest is certainly a great merit, it may also trap one in what Duhem memorably described as the 'gossip of the moment', hardly ever the harbinger of depth. Is it really a sign of profundity to give, as Peacocke does, so much and sympathetic attention to a recent interpretation of 'Yahweh' as meaning 'He who makes things happen' and ignore at the same time its long-standing interpretation as Existence Itself, an interpretation that played a crucial role in the history of Western thought? At any rate, if the provenance of 'Yahweh' must be sought in the political experience of the people, the question arises as to why other Semitic tribes, equally battered, failed to formulate it? Peacocke does not face up to this question, nor does he take a recourse to revelation, which incidentally, is mentioned only once throughout the book. A curious feature, because the last two chapters, on ecology and hope, respectively, are pivoted on the uniqueness of Jesus which Peacocke portrays over half a dozen, not too impressive pages, and because it is his stated view that in his lectures 'there are involved . . . a sequence of theological themes . . . that echo credal phrases from the Book of Common Prayer' (page ix).

Those phrases, from creation through redemption to final consummation, take on, as articulated by Peacocke, a distinctly phenomenological ring. This is not to suggest even the slightest doubt about his deep commitment to the Creed. But no doubts could be raised on that score about Henry Longueville Mansel, author of *The Limits of Religious Thought*, the Bampton Lectures for 1858. Yet, an Oxford don, apparently of some stature, was heard to remark: 'I had not expected to live to hear atheism preached from the pulpit of the University' (see V. F. Storr, *The Development of English Theology in the Nineteenth Century 1800-1860*; Longmans, Green: London, 1913; page 422). Not that Mansel would have wanted to give the slightest comfort to atheists, or to anticipate a religion without revelation. But as that perceptive don realized — and long before the inner logic of Mansel's highly applauded lectures dawned on all — the premises on which he built could not accommodate a reasoned account of Christian revelation. Classic illustrations of the inexorable force of that logic can be gathered not only from theology and philosophy, but also from the sciences. The road is straight from Descartes to De la Mettrie, from Luther to Schleiermacher, from the early Copenhagen school to the multiworld-theory and the Tao of physics.

An ominous-looking logic may raise its head out of Peacocke's position on the

mind-brain relationship, an inevitable consequence of his unqualified endorsement of the philosophy of emergent systems based on the work of Prigogine and others. To throw a strong light on this possibility, it may not be amiss to recall a remark which Herbert Feigl, the chief modern articulator of the identity theory of the mind-body relationship, made to the author of a book in which the case for dualism is unabashedly argued throughout: "Of course, I could not disagree more with you. Unfortunately I cannot do even that when reading some professedly Christian theologians on mind and body. I am unable to comprehend their contention that their position is different from mine". Needless to say, Feigl's position is compatible only with a religion without revelation as meant by Huxley. As to dualism, which Peacocke considers only in the perspectives of demonology and witchcraft, it is, in his eyes, an invitation to physicalist reductionism. This is certainly true of that parody of dualism produced by Descartes, a point not specified by Peacocke, who fails to mention even passing other formulations of dualism. He opts for the identity theory, which he introduces with appreciative words on materialism and monism. His sole effort to retain the mind (soul) is a brief reference to the conceptual irreducibility of mental experiences to empirical parameters.

This is hardly enough, as would be noted by those taking a long look both in Pusey Street and South Parks Road, respective symbols, in Peacocke's phrasing, of theological and scientific strongholds. They would point out that to discourse on an issue so crucial both to revealed religion and to religion without revelation as is the true nature of the mind-brain relationship, it is not enough "to note from the stands certain aspects of the state of the play". Peacocke states in the same breath: "I would not presume to enter the lists of that fearsome tiltyard from which so many, more competent and distinguished philosophically than I am, have retreated to lick their logical wounds" (page 128). Wounds cannot be escaped as long as one truly joins the battle for truth. At most they can be kept disinfected by making one's position clear and thoroughly considered.

The absence of these two qualities undercuts time and again Peacocke's efforts. A subject like creation and the world of science brings one into encounter at every turn with that philosophy which cannot be done justice with the evasive remark that the case for a qualified realism, adopted in these lectures, "cannot be presented here" (page 22). This transparent tactic is in sight again after a long section on time as perceived in science (evolution) and in theology (eschatology): "The philosophical discussion of time is beyond our present scope" (page 334). Even natural-scientist readers, not overly sensitive to philosophical rigour, may feel uneasy on finding Peacocke declare in the

next-to-last chapter that he had until then used the word nature "without any attempt to define it". After all, he himself tells his readers that several decades ago two scholars listed no less than sixty-six meanings of "nature", a number that could since then only increase.

A perhaps trivial, but telling sign that Nature is not static. Of this, Peacocke's book is a spirited and well-informed reminder. But in order to mean anything, Nature, and certainly man's nature, must retain some identity across the welter of change, especially if change is a true growth. Had Peacocke considered this basic philosophical issue, the touchstone of the truth of realism, with the seriousness it demands, his never-dull effort to portray

the dynamism of world and man as "being-in-God" would have secured more persuasiveness for *pan-en-theism*, the label by which he wants his message to be known. The proofs of his book may have been read with unusual speed, though, undoubtedly, not with an eye on Canon Bampton's final stipulation: "the Preacher shall not be paid, nor be entitled to the revenue, before his sermons are printed." □

Lives of the stars

J.H. Manley

The Uranium People. By L.M. Libby. Pp. 384. (Crane, Russak/Scribner's: New York, 1979.) \$15.95. To be published in the UK in May 1980 by Adam Hilger, at £8.50.

It is easier to convey what this book is not than what it is. It is not a novel though it would be better and less offensive if it were. It is not in the category of memoirs, for although there are personal recollections, there is also a liberal use of the personal accounts of others. The reader will find the distinction between these two sources very un-sharp and will slowly learn that the geographical chapter headings have more to do with the subject treated than the location of the author. It is not a historical work in spite of the impression conveyed by the inclusion of references. Even these are inconsistent

with a historical work. Some quotes are unreferenced; practically none to official papers and compilations are included. In addition one is aware throughout of the intrusion of the author's opinions and tastes in people and events rather than the balanced pro and con of the careful historian or the insightful analysis of the biographer. The fact that the book grew out of a series of lectures as a university visitor suggests that the material and style were meant to be entertaining to students. I believe they were. There are many anecdotes, some amusing, some instructive, some flat. The author's statement of her purpose is to "tell not only what was scientifically interesting about the uranium-plutonium project but what was human and interesting about the people involved". Let us therefore consider her treatment of people and events.

SCIENCE AND ... New Books from MIT

Science and Understanding

Books for Nonspecialists

MONSTERS IN THE SKY

by Paolo Maffei
translated by Mirella and
Riccardo Giacconi

"Maffei's 'Beyond the Moon' (1978) gave readers a tour of the natural order of the universe and was something of a sleeper among books on modern astrophysics. His new work, which is a more sophisticated examination of the subjects treated in 'Beyond the Moon,' ... progress[es] from the enigmas presented by relatively near comets to the mysteries of astoundingly remote 'monsters' such as supernovae, runaway stars, quasars, BL Lacertae objects, Seyfert galaxies, etc. The updated study of the black hole hypothesis may top anything written on the subject thus far."—*Publishers Weekly*
147 illus., £8.95

THE CYBERNETIC IMAGINATION IN SCIENCE FICTION

by Patricia S. Warrick

"*Cybernetic Imagination in Science Fiction* shows an amazing combination of understanding of cybernetics and of science fiction. ... It sets a new high standard for clear, literate, and thoughtful consideration of the field."—*Isaac Asimov*

Warrick examines over 200 short stories and novels written between 1930 and 1977 which portray computers as robots, as "thinking machines," as heroes and villains, gods and demons.
£9.30

BIBLICAL GAMES

A Strategic Analysis of Stories in the Old Testament
by Steven J. Brams

God plays games, and His behavior can be comprehended through the application of modern game theory. This is the insight of *Biblical Games*, a new approach to understanding the Scriptures and one of the first attempts to use an important scientific theory to elucidate human values.

"A remarkable book which furnishes deep insight into the Bible." *William Ted Martin*, Senior Lecturer, Professor Emeritus of Education and Mathematics, MIT

"This fascinating book on biblical games sheds light on why these Bible stories have intrigued people for so long and continue to do so."—*Kenneth E. Boulding*, Distinguished Professor of Economics, University of Colorado, Boulder.
£9.30

Science and Philosophy

A WORLD ON PAPER

Studies in the Second Scientific Revolution
by Enrico Bellone
Foreword by Stillman Drake

Introduces the concept of "the scientist's dictionary" and discusses major episodes in the "second scientific revolution" which occurred largely in the 19th century, with special attention to the great Kelvin-Boltzmann debate on the relative importance of experiment and theory in arriving at an understanding of reality. "Bellone makes his case with great urbanity and careful scholarship, based on detailed case studies. A thought-provoking and civilizing book."—*Gerald Holton*, Professor of Physics and of the History of Science, Harvard University
£9.30

THE ENTERPRISE OF KNOWLEDGE

A Essay on Knowledge, Credal Probability, and Chance
by Isaac Levi
£17.00

Science and Behavior

BIOLOGICAL STUDIES OF MENTAL PROCESSES

edited by David Caplan

These contributions by linguists, psychologists, and neuroscientists explore the new concepts and themes that extend and revise our former ideas about the biology of cognition.
£15.50

SEXUAL DIFFERENTIATION OF THE BRAIN

by Robert W. Goy and Bruce S. McEwen

A thoughtful and balanced account of the relative influence of chemistry and environment on humans, which provides new information on sex differences in brain structure that arise as a result of the action of gonadal steroids during the critical period in both birds and mammals.
£10.85

THE PURPOSIVE BRAIN

by Ragnar Granit

This book, by Nobel laureate Granit, describes the physiology of vision and principles of visual perception, and the control of motor activity to demonstrate the thesis that the underlying principle of brain activity is purposiveness. "Granit has written a book that should be required reading for all investigators of the central nervous system."—*J. C. Eccles, BioScience*
£7.55 hardcover;
£3.70 paperback

Science and Computers

THE COMPUTERIZATION OF SOCIETY

by Simon Nora and Alain Minc
Introduction by Daniel Bell

The English translation of the best-selling French report to Valéry Giscard d'Estaing on the impact of computers and communications technology on French society. "... should be of interest to political scientists, policy makers, and communications analysts."—*Library Journal*

Circle No. 53 on Reader Enquiry Card.

The title suggests an emphasis on people and the text starts that way. I confess to disappointment in Libby's efforts to describe people. Practically all the individuals for whom she implies a personal acquaintanceship are also known to me, some less well, some better, but I did not recognize them very well as portrayed. I finally concluded that at least part of the reason is her often tasteless and tactless choice of anecdotes used to suggest interest in so-and-so. There is a strained and misguided effort to make people seem more human by calling attention to uncommon mannerisms or recounting stories which are easily called crudities of various degree. Mention of an instance in which Laura Fermi listed the inner organs of a turkey says nothing about her graciousness. The worst crudity, an episode used to explain a facet of graduate student collective mores, involves the death of a colleague. To a point, foibles help to visualize a person and may make him interesting, but other less curious personality descriptions are needed for balance. These are missing, and even the non-anecdotal information is confined largely to physical characteristics. Rarely are adjectives relating to character used. In one case she explains that a person has been called a "delta-function of sympathy" but even an included definition of that term does not bring much of the person to the reader. In the sense that common gossip more frequently delights in communicating less desirable human traits as well as being idle, many of Libby's descriptions are gossipy. The less favour in which she holds a person the more gossipy the material. Leo Szilard as an individual is not crystallized by a good explanation of the Szilard-Chalmers effect. Fortunately the inclusion of a quote about him from Jacques Monod contributes excellently. Similarly, General Groves becomes more real through a quote from Emilio Segrè.

One could wish that at least a few of the people might have received the kind of thorough, thoughtful and sensitive treatment Nuell Pharr Davis achieved in *Lawrence and Oppenheimer* (Simon and Schuster: New York, 1968). The difference is all the more remarkable when one realizes that Libby lived and worked with many of her people, but Davis became acquainted only by interview, albeit with an impressive list of individuals. *The Uranium People* is a misleading title. It is more about events and stories of people, with little attempt to examine the humans at any length or the subtle reasons why they so frequently found each other interesting.

Events fare better in this book than people. Descriptions of places though not extensive are well written and convey correct images; so with technical explanations, some of which may not be essential to the lay reader. With few

From left, Ernest Lawrence, Enrico Fermi, J.I. Rabi at Los Alamos lodge.

exceptions I found no serious errors of historical or scientific fact. Use of many interesting memories of the author and of others makes a readable story. As with people, the interpretation of events is well tinted by the author's personal preferences and opinions.

Scientific-military-industrial roles in the project are discussed in several places, most frequently in terms of good scientists and bad military and industrial people, though not consistently so. One episode described contains speculation on a possible not-quite-right cosiness between General Groves and the engineering firm of Stone and Webster. This gets confusedly related to Arthur Compton and God, to a belief of a number of Metallurgical Laboratory scientists that industry need play only a minor role and to a jibe at Groves for depriving Compton of responsibility for weapon research and development in favour of Oppenheimer. It was surely naive of the scientists (including the author) to think that the production reactors and extraction facilities could be designed and built by them with a few hundred engineers and draftsmen. Libby implicitly acknowledges this in a later description of the DuPont achievement of completing this technical task including a city to house 60,000 construction workers all in 18 months. However, she has no appreciative word for Groves for his wise and effective choice of this contractor. The account of Groves' shift of weapon responsibility is quite wrong. After May 1942 Oppenheimer and I were sharing responsibility for the geographically scattered weapons work under Compton.

In a few months it became very clear that the work would be hopelessly behind unless it were centralized in a new laboratory with proper facilities. Compton concurred completely and fully supported our view to Groves. It was obvious that he could not carry the responsibility for two widely separated laboratories; a search for a Director was initiated and Oppenheimer chosen with complete approval of Compton. I felt he was glad not to have the weapon project.

The last chapters of the book cover such events as the establishment of the Atomic Energy Commission, the Russian A-bomb, and the H-bomb controversy and aftermath; and there is a chapter on atomic power. The style of writing continues, perhaps intensifies. Groves remains a bad guy until she can report his departure from the atomic scene with words symptomatic of her approach: "General Groves had put down Arthur Compton. Now his own boys, Robert Oppenheimer, Bush, and Conant had put him down. And soon, Oppenheimer was to be put down, in turn, by the Grey Board". Gentle, understanding, sympathetic! Libby finds it "hard to understand how the General Advisory Committee, chaired by Oppenheimer, could have persuaded itself to have voted negatively on the question of whether the United States should make an urgent programme to develop the thermonuclear bomb". At first one thinks that perhaps she did not pay enough attention at the time and then later failed to read Herbert York's careful and extensive examination of this and associated issues in *The*

New Biology titles from Edward Arnold

Quaternary Palaeoecology

H.J.B. Birks and Hilary H. Birks

This book describes the study of past ecosystems, using a variety of methods to reconstruct the past flora and fauna and, by careful inference, the environment. Special emphasis is placed on pollen analysis since pollens are the most abundant organic remains preserved in Quaternary sediments.

Boards £28 Publication June

Environmental Biology

E.J.W. Barrington, FRS

Resource and Environmental Sciences Series

An introduction to biology for those with little or no background knowledge. Progressing from the origin of life through the biochemical, ultrastructural, physiological, ecological and evolutionary levels, the approach throughout is to relate structure and function to the ways in which organisms interact with their environments.

Paper £5.95 Publication June

Studies in Biology 40 Endogenous Plant Growth Substances

Second Edition

Thomas A. Hill

General introduction to plant hormones, outlining the present state of knowledge and showing some of the ways in which the problems of their study have been approached. New material includes the development of new techniques for extracting these substances and their metabolites, a section on the mechanisms of action of cytokinins, abscisic acid and ethylene and examples of the applied aspects of plant growth hormones.

London WC1B 3DQ

Advisors (Freeman: San Francisco, 1976). Further on, however, she has included a selective quote from him but not his conclusion that the advice of the Committee was "sound and right". She also writes: "One may ask how the GAC members, strongly opinionated scientists, could have so changed their vote on the hydrogen bomb in a couple of weeks". Reference is then made to a meeting on 29 October and then to a "second meeting". Actually, there was no change of vote, and the written views, unanimously against an all-out effort, are dated 30 October. If entertainment is the objective of Libby's book, perhaps these details are unimportant, but I view such distortions as poisonous. The student and the serious reader must take something like York's book as an antidote; then Libby's continued loyalty to "one of my heroes", Edward Teller, can be set in contrast to York's development from his early career as the first director (1952-57) of Teller's

Lawrence Livermore Laboratory to his subsequent activity in arms control and disarmament.

The Uranium People is interesting in the same sense that movie magazine stories about the stars are interesting. However, events and people, now for the most part passed into history but leaving a legacy which still affects our world, have a different kind of interest and deserve a different kind of treatment. □

J.H. Manley became active in nuclear physics at Columbia as a faculty member with I.I. Rabi, John Dunning and others in 1934, and joined the Metallurgical Laboratory at Chicago under A.H. Compton in January 1942 while on leave from Illinois. He assisted J.R. Oppenheimer in planning and establishing the Los Alamos Scientific Laboratory, to which he moved for what turned out to be a total of 23 years before becoming a consultant — his present status. He was Executive Secretary of the General Advisory Committee (USAE) during the first four years of Oppenheimer's chairmanship.

Descent is what matters

David L. Hull

The Darwinian Revolution: Science Red in Tooth and Claw. By Michael Ruse. Pp.320. (University of Chicago Press: Chicago and London, UK, 1979.) £12.

MOVIE reviewers like so few movies because they see too many of them. For the same reason, academics write very few favourable reviews of books, especially if the book is in their own area and is directed at a general audience. It is difficult to believe that yet another book on Darwin and the Darwinian revolution could add anything new or contain any surprises. Ruse's book is an exception on all counts. Darwin scholars and the general reader alike can learn from it.

In the first half Ruse describes the state of science before the *Origin*. Historians argue that scientific views must be set out in their own terms, not biased towards the use which later scientists will make of them. That is easier said than done. Ruse cannot discuss every topic of interest to scientists in the first half of the nineteenth century. Understandably he limits himself to those areas of science which eventually contributed to Darwin's theory of evolution — Charles Lyell's uniformitarian geology, Richard Owen's archetypal theory, Karl Ernst von Baer's embryology, and so on. In certain cases, Darwin incorporated these views into his own. Just as often his ideas were shaped by

reacting against the views of his predecessors. But, in any case, once Ruse has narrowed his focus, he discusses the science in its own right, not biased towards the use which Darwin eventually made of it. Although Ruse teases us a bit along the way, he does not get around to Darwin and his theory until the middle of the book. All the attention which Ruse pays to the scientific work which preceded Darwin, instead of detracting from the magnitude of Darwin's own contributions, only enhances it.

Another strength of Ruse's exposition is his concern with the impact that social factors had on both the formulation and the reception of Darwin's theory. However, the 'society' of greatest interest to Ruse is not Victorian society at large but the society of scientists. Darwin was caught up in the groundswell as science in Great Britain became self-consciously a profession. Young scientists today can only envy the ease with which budding young scientists in Darwin's day were able to step into the innermost circles of science. To begin with, relatively prosperous Victorians were a tightly-knit group. For example, the first three directors of Kew Gardens were William Hooker, his son J.D. Hooker, and William Thiselton-Dyer, the younger Hooker's son-in-law. J.S. Henslow was the first scientist to have significant influence on Darwin, and J.D. Hooker was his first convert to evolutionism. Henslow married the sister of Leonard Jenyns, the man who had been offered the position of *de facto* naturalist on the *Beagle* before Darwin. Their daughter in turn married J.D. Hooker. Upon her death, Hooker married the widow of William Jardine, a famous ornithologist. Darwin married a Wedgwood,

and so it goes. Of equal importance, so few young men were inclined or financially able to contemplate a life of science that the ones who did were welcomed enthusiastically.

Darwin began his career as a Lyellian geologist. In retrospect we tend to think that Lyellian uniformitarian geology was more successful than it actually was because the first histories of geology were written by uniformitarians. To the victors goes the history. But in fact Darwin was one of the few young geologists at the time who accepted Lyell's views. Darwin's early work on the formation of coral reefs (which turned out to be basically correct) and the parallel roads of Glen Roy (an embarrassing blunder) was in the Lyellian mould. Gradually, however, Darwin became his own scientist, departing in several important respects from Lyell. By 1859 not only was Darwin a professional scientist with a well established reputation, but also he had "built around himself a new scientific community from which his evolutionism could be launched" (page 185).

One of the great puzzles in science is why certain scientists succeed in converting their fellow scientists when all their precursors failed. For example, Lamarck's theory was greeted with derision, Robert Chamber's *Vestiges of the Natural History of Creation* was condemned by everyone who was anyone, including T.H. Huxley, and Herbert Spencer's musings about the transformation of homogeneity into heterogeneity produced little more than embarrassed silence. Ruse gives many reasons for Darwin's success — such general considerations as the changes wrought by the industrial revolution and the rise of naturalistic metaphysics to such specific considerations as the way in which Lyell posed the species problem in his *Principles of Geology* — but of prime importance was the professional manner in which Darwin conducted himself and presented his case. Lamarck had destroyed his credibility by tossing out theory after theory in areas in which he knew nothing; Chambers was the Velikovsky of his day; and Spencer was a "philosopher". But Darwin was a scientist, writing as a scientist, for scientists. Nineteenth-century views on the nature of science had as much to do with the reception of Darwin's theory as religion and the fossil record.

The most entertaining part of Ruse's exposition is the attention he pays to the interpersonal relations between the scientists of the period. Although Owen initially helped the young Huxley in his career, he soon came to be Huxley's chief enemy. Because the Darwinians won, everyone knows what an unpleasant man Owen was, but Huxley too had a mean streak. After Owen tried to block the publication of one of Huxley's papers, Huxley used his review of the *Vestiges* to attack him. As Ruse sees it, the animosity between Huxley and Owen was as much

responsible for Owen coming out against Darwin as the content of Darwin's theory. "At the scientific level Owen was determined to oppose Huxley, and if Huxley was to support Darwinism then so be it" (page 144). Ruse also mentions, possibly to neutralize anti-Owen propaganda, that "at least until 1853 — when Huxley started attacking Owen and when Darwin and Huxley became close — there was warm feeling between Darwin and Owen" (page 144). The source of this claim is the following remark which Darwin made in a letter to Huxley in 1854 about Huxley's review of the *Vestiges*:

By Heavens, how the blood must have gushed into the capillaries when a certain great man (whom with all his faults I cannot help liking) read it!

This is warmth of sorts.

One of the chief messages of evolutionary theory as a biological theory is that descent is what matters, not abstract similarity. Ruse applies this same principle to the history of science. No scientist has suffered more from the effects of the antiquarian disease known as "precursoritis" than has Darwin. Endless energy has been expended to uncover precursor after precursor — authors who happened to mention in passing one or more views similar to those later enunciated by Darwin. More recent historians have complained that often the putative similarity is spurious. But the important point is that ineffectual precursors do not count. As Ruse argues, "it would be a mistake to think that the most significant intellectual continuity in the Darwinian Revolution existed among those one would label 'evolutionist'" (page 199). The real precursors to Darwin were not Lamarck, Erasmus Darwin, William Wells, Patrick Matthew and Edward Blyth. Darwin was totally unaware of the work of several of these men, and the others had little effect on him or anyone else. Darwin's real precursors were Lyell, Henslow, Owen, Herschel, Whewell, von Baer and Sedgwick. These were the men who contributed to the Darwinian revolution. What counts in the history of science is continuity of effect, not similarity of ideas. Likewise, as Ruse remarks, a "Darwinian" is "someone who identified with Darwin but not necessarily someone who accepted all of Darwin's ideas" (page 203).

During the past decade, Darwin scholars have increased our understanding of Darwin and the Darwinian revolution immensely. Ruse gives his readers the benefit of that scholarship without making them suffer under the burden of the tedious pedantry which usually accompanies it. □

David L. Hull is Professor of Philosophy at the University of Wisconsin-Milwaukee, Milwaukee, Wisconsin.

Full of hope and promise

R.V. Short

The Politics of Contraception. By Carl Djerassi. Pp.274. (W.W. Norton: London, 1980.) £6.50.

CARL DJERASSI, one of the world's outstanding organic chemists, has written a most important book about contraception that makes compelling reading. It deserves the widest possible audience, not only throughout the scientific community, but far beyond, in the realms of policy-makers, politicians, journalists, administrators, funding agencies, and indeed amongst all who are concerned about world futures. There are few indeed who have mastered the art of popularizing important issues without seeming to trivialize them; this book stands out as a rare example of scientific reporting at its very best. Djerassi's writing reflects the man himself — forthright, scholarly, direct, uncompromising, and with an outstanding ability to single out important issues for critical comment. He shares with Samuel Pepys "a fine conceit" that adds to, rather than detracts from the narrative, because one respects the integrity and intellect of the man behind the pen.

Carl Djerassi.

Djerassi tells us that he has aimed to produce "not a scholarly treatise, but the distillate of the conclusions and opinions of a person who for over 20 years has lived a bigamous professional life in serving simultaneously as a professor carrying out basic research and as an industrialist who has had to concern himself with finding worldwide applications for laboratory discoveries". Not only has he been able to combine the viewpoints of a professor of organic chemistry with those of a director of a pharmaceutical company, but he has added profound biological and social insights; it is to this amalgam of talents that we must attribute his success as an

international entrepreneur, and the wide appeal of this particular book.

Djerassi will long be remembered for an article he wrote in *Science* in 1970 (*Science* 169, 941-951) entitled "Birth control after 1984", and his book is an extension and development of the ideas put forward in that article. The need to redouble our efforts in contraceptive research and development is self-evident at a time when the world's population is still continuing to increase by about 150,000 people a day; this single fact still continues to pose the greatest threat to the peaceful co-existence of mankind in the future.

Our principal goal must be to develop new approaches to contraception capable of deployment on a massive scale to meet the needs of the developing world; of relatively minor importance is the improvement of methods that we already have in the West, so as to maximize their efficacy and minimize their attendant health hazards. But unfortunately it is our obsession with these latter objectives in developed countries that has seriously impeded research into new contraceptives. Much of this research must inevitably be carried out in the West, because it is only in the developed countries that we have all the necessary facilities, funds, and trained minds, together with the industrial know-how to exploit the discoveries. Herein lies the dilemma. In the first place, the declining rate of population growth in Western nations has allayed public and political concern for the problem, so that governmental support for research has now switched to more immediate problems such as alternative energy sources. This change in emphasis has coincided with the development of a plethora of governmental regulations about drug safety, and the establishment of a bureaucracy to enforce them. The statutory requirements for long-term animal toxicity testing before a drug can be marketed means that it may take from 10 to 17 years between the discovery of a compound, and its approval for clinical use by the regulatory agencies. Thus it is hardly surprising that new product development in the contraceptive field has become one of the least attractive areas of research for the pharmaceutical industry; but without the active involvement of industry, our hopes of any significant new contraceptive developments are faint indeed.

In our national drug regulatory agencies we have created organizations who have absolute power, but no sense of responsibility to see that a compound that is desperately needed is ultimately marketed; witness the status of the injectable contraceptive Provera. Surely we need to establish some mechanism whereby the pharmaceutical industry and the regulatory agencies could have a common cause once it has been agreed that there is a need to develop drugs to meet a particular demand. Under the present system, the regulatory agency acts as State

prosecutor, and private industry is the defendant. The case only comes to trial after years of time and effort and, as Djerassi points out, the pharmaceutical company does not have a friend in court. Surely there would be much to be gained by exchanging the trauma of a final examination for some type of continuous assessment?

Although agreeing with the need for governmental regulations about drug development and safety testing, Djerassi highlights the bureaucratic stupidity of some of the consequences. For example, the US Food and Drug Administration's requirements for condoms have meant that America produces the thickest condoms of any country in the world; if standards were relaxed to permit a 1% increase in the incidence of pin-holes, condom thickness could be reduced by half, and the increased risk of pregnancy resulting from this would only be one conception per 2.5-5 million acts of coitus. The instructions that now must accompany each packet of oral contraceptives are almost unintelligible even to the expert, and Djerassi contrasts this to the simple and effective wording that is used in China. Indeed, the chapter devoted to birth control in China is one of the most fascinating and challenging in the whole book.

Djerassi inevitably paints a rather gloomy picture about our ability to develop those new approaches to contraception which we so desperately need. But he may be unduly pessimistic, as he has based his strategies for the future on a logical planned approach of contraceptive research and development, and has ignored the major role that accident and chance can take in such affairs. For example, we can derive some comfort from the fact that in

reviewing probable future developments in the field, Djerassi does not even mention what to many seems to be the most exciting hope for the future, the use of analogues of gonatrophin releasing hormone. It has recently been shown that daily administration of microgram amounts of one of these peptides can effectively inhibit ovulation for long periods of time in monkeys and in women. Here we have an example of a serendipitous discovery; these readily synthesized, non-toxic, non-steroidal compounds were developed by the pharmaceutical industry for the treatment of some forms of infertility, but paradoxically they can also be used as contraceptives. As they have already passed many of the drug regulatory agencies' hurdles, and are on the market in some countries, they could be available for widespread clinical use within a few years from now.

So the future is full of hope and promise, provided that the West can increase its funding for contraceptive research, and remove the existing bureaucratic impediments to commercial development. But there are many obstacles to be overcome if we are to develop a rational approach to contraceptive research and development, and the world must be indebted to Carl Djerassi for pointing out some of the illogical constraints we have imposed upon ourselves. There can be no doubt as to the truth of his general conclusion that it is the politics of contraception, rather than the science, that now plays the dominant role in shaping the future. □

R. V. Short is Director of the Medical Research Council Unit of Reproductive Biology, Edinburgh, UK.

The micro future?

Stuart Sutherland

The Mighty Micro. By C. Evans. Pp. 255. (Gollancz: London, 1979.) £5.50.

OVER the past 20 years, many voices have noisily if somewhat prematurely hailed the advent of the computer revolution. It has had no more enthusiastic advocate than the late Christopher Evans, whose premature death occurred after *The Mighty Micro* had been published. It has for long been customary to place the revolution about two decades after the date at which the prediction is made, and Dr Evans adheres to this convention. By AD 2000, we will have, according to him, universal electronic mail, greatly improved Prestel sets on our wrists, and permanently worn silicon chips to monitor our health and automatically inject corrective drugs as needed. Money will have been abolished

since all financial transactions will be computerized, and computers will administer psychotherapy and justice as well as taking over the function of the teacher: bookshops and libraries will no longer exist, since it will be possible to call up anything ever published on your drawing-room VDU.

The Mighty Micro is written for the general public, not for the specialist. It is lively and entertaining, but makes no attempt to describe how a silicon chip works nor does it provide any insights into the intricacies of computer software. It contains some good anecdotes about the forerunners and pioneers of computing — Babbage, Hollerith, Zuse and Schreyer (who developed special-purpose computers in Germany in the Second World War), Aitken, Turing and Von Neumann. The pioneers saw a visionary

Society for Applied Bacteriology Symposium Series No.8

Microbiological Classification and Identification

edited by M. Goodfellow and R.G. Board

June/July 1980, xiv + 396 pp. £17.50 (UK only)/\$40.50 0.12.289660.2

This volume, the eighth in the SAB Symposium Series, answers the need for a comprehensive examination of the impact of modern taxonomic methods on the classification and identification of important groups of organisms. It offers, for the first time, a coherent view of a difficult subject of considerable significance. The information is detailed and up-to-date, and covers methods such as numerical, genetical and chemical taxonomy. It highlights the value of nucleic acid homology and base ratio determinations, and considers the contribution of biochemical and morphological techniques. The significance of plasmids on the process of classification and identification is also discussed. The chapters are written by leading specialists from a variety of disciplines; their contributions will stimulate interest far beyond the confines of these particular areas, and will help to re-establish taxonomy as a deserving field of research in its own right.

Probability and Mathematical Statistics: A Series of Monographs and Textbooks

Statistical Inference for Stochastic Processes

I.V. Basawa and B.L.S. Prakasa Rao

June/July 1980, xvi + 438 pp. £26.80 (UK only)/\$62.00 0.12.080250.3

The current decade has witnessed an exponential growth of literature on stochastic processes. However, much of the work seems to be dominated by theoretical models which lack immediate appeal from a statistical point of view, and as a result a gap has developed between theory and applications. The aim of this book is to reduce this ever-widening gap by directing the interest of researchers in the area to the inferential aspects of stochastic processes. The authors have here attempted to put on record the work illustrating the current state of the art.

Monographs of the Physiological Society No.37

Local Mechanisms Controlling Blood Vessels

W.R. Keating and M. Clare Harman

June/July 1980, viii + 142 pp. £11.80 (UK only)/\$27.00 0.12.402850.0

Research undertaken during the last fifteen years has shown that blood and lymphatic vessels, and mammalian arteries in particular, are controlled by much more organised and complex local mechanisms than had previously been realised. These include specialised functions of inner and outer smooth muscle, as well as electrical discharges with unusual features. These have only recently become clear enough to allow any coherent general analysis. This book aims to present such an analysis in a brief and convenient form, and provides extensive references for readers who wish to re-examine controversial details of the evidence.

Society for Applied Bacteriology Technical Series No.15

Microbial Growth and Survival in Extremes of Environment

edited by G.W. Gould and Janet E.L. Corry

June/July 1980, xvi + 244 pp. £16.00 (UK only)/\$37.00 0.12.293680.9

This volume presents the contributions made at the Autumn Demonstration Meeting of the Society for Applied Bacteriology in October, 1978. It brings together current research and modern methods and techniques used by microbiologists and biochemists dealing with diverse research problems, but sharing an interest in microbial growth and survival under extremely unfavourable conditions. The extreme environments discussed vary greatly in type, ranging from hot to cold, acid to alkaline, low to high water activity and raised osmotic pressure, dry, saline and sugar-rich. Other papers are concerned with chemical and biochemical extremes, including high levels of toxic chemicals and hyperbaric oxygen. The somewhat neglected, but ecologically most important, environmental extreme of low nutrient concentrations in oligotrophic waters is also considered.

Biological Microcalorimetry

edited by A.E. Beezer

June/July 1980, x + 484 pp. £30.00 (UK only)/\$69.00 0.12.083550.9

Biological Microcalorimetry is an up-to-date account of microcalorimetry as applied to biological topics and gives a comprehensive review of this growing area of research. For non-calorimetrists it is intended as an introduction and for those already involved in calorimetry it provides a survey of other important biological studies. The topics covered range from 'pure' model biochemical systems to complex, intact biological systems such as blood: also included are discussions of both practical and theoretical problems. This book reflects the way in which research activities have changed and also the extent to which practising biologists have accepted calorimetry. The scope is wide and includes microbiological systems, tissue cells and drug interactions. There is, too, a concentration upon model studies, for example membrane, polymer and heat capacity studies.

Proceedings of the Sero Symposium No.29

Pituitary Microadenomas

edited by G. Faglia, M.A. Giovanelli and R.M. MacLeod

June/July 1980, xii + 565 pp. £30.00 (UK only)/\$69.00 0.12.248150.X

The importance of intrapituitary adenomas was established in 1932, although considerable progress has been made only during the last few years. Topics covered in the book include morphological and molecular features of hormone secretion in normal and tumoral cells in the pituitary, immuno-histochemical aspects, and pathogenesis of pituitary tumours. The discussions also deal with the study of receptors, the role of neurotransmitters in the control of pituitary functions, and neuroendocrinology and endocrinology of pituitary microadenomas. The diagnostic studies include endocrine function tests and radiology, while microneurosurgery, cryosurgery, alpha particle therapy and neuroactive drugs are treated in the papers on therapeutic methods.

The Bipyridinium Herbicides

L.A. Summers

June/July 1980, x + 450 pp. £30.00 (UK only)/\$69.00 0.12.676450.6

The bipyridinium herbicides, diquat, paraquat and related compounds, have attracted considerable interest over the past twenty years. This is the first book to be devoted solely to this important group of herbicides; it provides a comprehensive and up-to-date account of the published work in this area, and aims to put all aspects of their study into perspective. The book cites approximately 2500 references. The synthesis, chemistry, activity and applications of the herbicides are discussed in full, and toxicology, plant physiology and the mode of herbicidal action are also treated. These discussions involve a wide variety of disciplines. It will prove a valuable reference to all those interested in the bipyridinium herbicides, and particularly to researchers involved in chemistry, biochemistry, biology, agricultural science, soil science, toxicology, medical science, and environmental science. It should also be of interest to students as supplementary reading in these fields, and will be a necessary addition to many institutional libraries.

An Introduction to Spectroscopy for Biochemists

edited by S.B. Brown

May/June 1980, xvi + 404 pp. £16.60 (UK only)/\$38.50 0.12.137080.1

Over the past fifteen years there have been major developments in the application of spectroscopic methods to systems of biological and medical interest. Biochemical literature increasingly embraces spectroscopic techniques such as nuclear magnetic resonance, electronic spin resonance and circular dichroism. This book aims to provide a basis for understanding and evaluating such literature, and to create an awareness of the established and potential value of spectroscopy in solving problems. The principles of each technique discussed are presented in a straightforward and precise, yet largely non-mathematical style. Emphasis has been placed on a wide survey of the application and scope of the various branches of spectroscopy, which include vibrational, molecular emission, ultraviolet and visible, and atomic absorption, while references to further works are given at the end of each chapter.

Carbohydrate Sweeteners in Foods and Nutrition

edited by Pekka Koivistoinen and Lea Hyvonen

May 1980, xiv + 290 pp. £17.60 (UK only)/\$40.50 0.12.417050.1

Recent years have seen a rapid increase in the volume of basic and applied research carried out into carbohydrate sweeteners. This has led to the development of many new applications, on the technological side, while much more information concerning the health and safety aspects has also become available. The dominant role of sucrose as a sweetener has not yet been challenged but research is now expected to lead to the development of alternative means of sweetening foods. This important book will be required reading by professionals in the broad area of food science and other related fields. It is, in short, the most comprehensive and thorough source of information currently available about modern applications of sweeteners in food technology.

Advances in Ecological Research Volume 11

edited by A. Macfadyen

April/May 1980, xii + 430 pp. £25.00 (UK only)/\$57.50 0.12.013911.1

The subject matter of the articles in this series ranges over the whole field of theoretical and applied ecology, aiming to present the knowledge derived from primary research to a wide audience. The original papers are all reviews, bringing together the work of many researchers from different parts of the globe and offering previously inaccessible material. In this volume there is an emphasis on the animal kingdom, especially birds, mellanic insects and leafhoppers, while two articles on heavy metals and agricultural ecosystems stress ecosystem studies. This synthesis of recent research is relevant to many theoretical topics, such as evolution, predator-prey relations, island biogeography and species diversity. It will also stimulate and inform readers concerned with environmental management, from the experienced ecologist and agriculturist to the student, the layman and the politician.

Research Techniques in Nondestructive Testing Volume 4

edited by R.S. Sharpe

April/May 1980, x + 514 pp. £30.40 (UK only)/\$70.00 0.12.639045.1

In this volume, papers on ultrasonic attenuation, ultrasonic scatter, vibrational analysis and neutron scatter have been introduced; these are indicative of the growing interest in the extending scope and potential of nondestructive testing towards monitoring total microstructural uniformity. Advanced signal processing procedures and more computer and microprocessor control also feature increasingly; this marks a significant step forward from the empirical technology on which non-destructive testing has for so long been based. The series also serves to provide an important communications link between those directly involved with the design and use of nondestructive testing procedures in industry, and those in parallel fields of academic research.

Fibrous Proteins: Scientific, Industrial and Medical Aspects Volume 2

edited by D.A.D. Parry and L.K. Creamer

April/May 1980, xvi + 258 pp. £13.00 (UK only)/\$30.00 0.12.545702.2

Unlike volume one, which is essentially a reference work, this second book explores new areas of research and significantly contributes to the furthering of knowledge in this field. Emphasis has been laid on those areas of greatest current interest and which show the most potential for future development. The scientific, industrial and medical aspects of each of the following four subject areas are considered: muscle and meat, collagen and leather, keratin and wool and finally, 'other fibrous proteins' such as elastin, fibrinogen and silk. Although scientists working with different fibrous protein systems employ similar techniques, these topics are usually considered separately. Hence, this volume provides a rare opportunity for research workers not only to obtain up-to-date information on advances in their own field, but also to gain a valuable insight into development in related fields.

Myriapod Biology

edited by Marina Camatini

April 1980, xviii + 448 pp. £28.80 (UK only)/\$66.50 0.12.155750.2

Central though the myriapods are to an understanding of Arthropoda in general, most studies have neglected this fascinating group of invertebrates. The material presented here provides not only a review of the evidence recently achieved with a newer, functional approach, but also breaks new ground in its orientation towards the origin and evolution of the group, both as a separate entity and in relation to the arthropods. It is, moreover, the first volume to condense major topics into separate sections, dividing the presentations among themes such as cytogenetics, functional anatomy and embryology, ecology and biogeography, and endocrinology and life cycle. All sections place emphasis on the evolution of Myriapoda. The last section of the book is devoted to arthropodan evolution in general, and illuminates the stimulating effect exerted by interrelationships and the evolutionary history of these invertebrates.

Biomedical Research Applications of Scanning Electron Microscopy Volume 2:

edited by Gisele M. Hodges and Richard C. Hallowes

Volume 2 April 1980, x + 316 pp. £24.80 (UK only)/\$57.50 0.12.351002.3

The scanning electron microscope is a most versatile instrument for examining and analysing the microstructure of solid objects. It has proved to be of great value in studies of structure-function relationships in biological tissues as it can provide direct information on the morphology of cell surfaces in normal, pathological and experimentally induced situations. Although scanning electron microscopy is becoming a routine method in biomedicine, until now there has been no publication dedicated to a discussion of its applications. The purpose of this open-ended series is, then, to review and evaluate these applications integrating current knowledge of structure, composition and function into a comprehensive framework.

Experimental and Surgical Technique in the Rat

H.B. Waynforth

April 1980, xvi + 270 pp. £11.80 (UK only)/\$27.50 0.12.738850.8

This volume provides the first detailed collection of those methods most commonly used for rats in scientific research. Recently, surgery in the rat has developed many techniques, some simple, others sophisticated and intricate. The new researcher will find here an introduction to the range of techniques that are available, written in a way that will allow the book to be used as a bench manual. To this end, particular attention has been placed on the anatomy of the rat, details of the surgery involved and the post-operative care required. Although the techniques described apply principally to the rat, many of them can, with slight modification, be adapted to suit laboratory experiments with mice or guinea pigs. Great emphasis has been laid on illustrating each procedure. The provision of photographs and detailed drawings will be appreciated by scientists who have noted the paucity of visual guides in previously published literature.

Language Production Volume 1

Speech and Talk

edited by B. Butterworth

April 1980, x + 478 pp. £28.00 (UK only)/\$64.50 0.12.147501.8

This and the following volume will bring together all the important research on language production from the fields of adult and developmental psychology, diachronic and synchronic linguistics, phonetics, sociology, neurology and artificial intelligence. Volume 1 focuses on adult speech. A survey of research methods introduces the subsequent reviews which cover the social setting of talk, the psychological processes involved in planning and organizing utterances and the neuromuscular processes that give rise to articulation. Methodologies and materials that apply to the central issues in speech production are in many cases brought to bear for the first time. Traditional research methods are also represented in chapters on aphasia, the significance of hesitations and slips of the tongue, and on motor control of articulation. A final chapter summarizes the implications for a psychological model of speech production.

Royal Society of Medicine International Congress and Symposium Series

Human Health and Environmental Toxicants*

edited by C. Wood

April 1980, xii + 210 pp. £15.60 (UK only)/\$36.00

0.12.794919.4 (Academic Press)

0.8069.1235.6 (Grune & Stratton)

This volume presents the proceedings of a conference held on 14-16 May 1979. The subject of this meeting is one which is currently of great concern to both doctors and industrialists, namely, the potential health hazards of modern technology. As Lord Smith of Marlow said in his introductory address "... not only is it extremely difficult to identify the main areas of significant risk; it is difficult to define what constitutes a risk, and still more difficult to say what is an acceptable level of risk. There is a certain balance between risks and benefits, within which it is not only wrong to ignore hazard but also wrong to exclude major benefits to mankind through unreasonable exaggerations of hazards." It was the development and maintenance of this balance, within the context of society as a whole, around which much of the discussion at the meeting centred.

Annals of Botany Supplement No.1

Aspects of the Structure, Cytochemistry and Germination of the Pollen of Rye (*Secale cereale* L.)

J. Heslop-Harrison

January 1980, 48 pp. 18 Plates, £7.80 (UK only)/\$18.00 0.12.344950.2

Despite the importance of the grasses in the human diet, many basic features of their biology remain to be investigated. This is true for aspects of the reproductive physiology of the group, and notably for those connected with pollen, the pollen-stigma interaction and pollen-tube growth. This memoir reports some of the results of recent work on the structure and germination of the pollen of rye and other grass species. The treatment itself is experimental in nature as it combines something of the character of both research paper and review. This is the format envisaged in launching this new series of supplements to *Annals of Botany*. The supplements offer authors the opportunity not only to report new findings, but also to relate them to those of other workers in more detail than is usually possible within the confines of the normal research paper.

American College of Laboratory Animal Medicine Series

Spontaneous Animal Models of Human Disease 2 Volumes

edited by Edwin J. Andrews, Billy C. Ward and Norman H. Altman

Volume 1: November 1979, 322 pp. £30.60 (UK only)/\$52.50 0.12.058501.4

Volume 2: February 1980, 328 pp. £30.60 (UK only)/\$52.50 0.12.058502.2

This two-volume work gathers together the diverse information presently available on spontaneous animal models of human disease. In addition to providing a comprehensive review of existing models, the book presents many previously unpublished new models. A conscious attempt is made to point out the similarities and dissimilarities of each model to its human counterpart. The authors discuss many long proffered models with regard to their limitations in biomedical science.

International Geophysics Series

An Introduction to Dynamic Meteorology Second Edition

James R. Holton

November 1979, 416 pp. £12.80 (UK only)/\$22.00 0.12.354360.6

The standard textbook in its area, *An Introduction to Dynamic Meteorology* has been considerably expanded and updated for this Second Edition. Holton approaches dynamic meteorology in a logical fashion as a coherent subject with a central unifying concept, namely, the quasi-geostrophic system. Quasi-geostrophic theory is used to develop the principles of diagnostic analysis, numerical forecasting, baroclinic wave theory, energy transformations, and the theory of general circulation. Throughout the text emphasis is on physical principles rather than mathematical elegance. Each chapter contains numerous problems and examples. Answers are included to selected problems. The text is addressed primarily to senior and beginning graduate level students in meteorology, but any student of the physical sciences who has mastered introductory-level physics and calculus will find the material accessible.

future for computing, but without the invention of the silicon chip their visions could never have been realized, and that invention, as Dr Evans points out, could never have been foreseen. It transformed the cost, speed and reliability of computers, and made it practical to multiply the components almost without limit.

Most of *The Mighty Micro* is devoted to the future, and is speculative rather than closely argued. Dr Evans relies heavily on analogies, many of them striking. To give the reader an idea of what the exponential growth in computers portends, he points out that a piece of paper folded on itself 50 times would stretch beyond the orbit of Mars, a result that few would guess without calculation. The analogy may be better than he realizes: just as there are practical limits to such exponential growth in the thickness of a piece of paper, so there are invariably factors that set limits to the continuing exponential growth of a new technology.

Perhaps the most obvious such factor is the provision of the sort of software Dr Evans envisages. He is surely being unduly sanguine when he writes "There is no suggestion that before substantial improvement [in machine intelligence] can take place, any new principles must be invoked or new discoveries made". It is true that advances in artificial intelligence have over the last ten years thrown some light on how the human brain is likely to execute certain tasks, but the mirage of actually using intelligent programs to do something useful constantly recedes from us and there is still only a handful of applications. One reason is that very few general principles have been discovered, and it is necessary to work out *ab initio* the structure of each new intelligent task before attempting to program a computer to execute it. Hence, computers have so far proved to be an effective substitute for the human brain only in tasks, such as mass spectrometry and chess, the structure of which has been made explicit and which necessitate a search through a vast number of alternative possibilities. Where, as in economic decision taking, we have little understanding of the task, computers cannot carry it out unaided, and are probably more of a hindrance than a help to our own thinking if used as a tool, since the spurious authority of computer forecasts may make us forget the fallibility of the assumptions on which the forecasts are based. As for Dr Evans' claim that we will shortly be able to design a machine that is more intelligent than ourselves and which can in turn design machines more intelligent than itself, we have at the moment no inkling of how to set about such a problem; nor is there any evidence to suggest that it would ever be possible. There remains, then, an astounding gap between the prognostications of some practitioners of AI and the performance of existing programs, and there is no sign of

The late Christopher Evans.

Courtesy of Victor Gollancz Ltd.

the impending discovery of a software equivalent of the silicon chip that will open the way to dramatic advances in the subject.

Although Dr Evans may have compressed the time scale, computers will inevitably change our living conditions; but his enthusiasm for the prospect will not be shared by everyone. He appears to think that the extra leisure time left when computers are performing most of both the important and the menial jobs can be filled by playing games against them: but people like to feel they are doing something useful and a life devoted to such games would be a hell of boredom. The Greeks, provided with leisure by slave labour, occupied themselves with making war on their neighbours, parochial politics and speculations about the nature of the Universe. We can no longer fill our time by making war, and if computers were ever able to take political decisions more sensibly than ourselves and to undertake advanced scientific work, it would come to seem pointless for us to engage in these activities. It is perhaps fortunate that in the lifetime of anyone now living we are unlikely to design our own intellectual successors, and hence render ourselves redundant. □

Illusions of pedigree

J.D. Mollon

Seeing: Illusion, Brain and Mind. By J.P. Frisby. Pp.160. (Oxford University Press: Oxford, 1979.) £6.95.

THOSE who teach experimental psychology will instantly recognize the pedigree of this handsome colt: it is sired by Richard Gregory out of Lindsay and Norman. It lacks the turn of speed of its parents but proves an excellent stayer on soft ground, is usually reliable over hurdles and should bring rewards to its backers.

Professor Frisby is to be congratulated on an engaging and remarkably lucid introduction to the problems of visual perception. His declared purpose is to combine the psychological, physiological and computational approaches to perception. He has a good judgement of the important issues. Topics covered in detail include feature detection, figure-ground differentiation, the anatomy and physiology of the visual cortex, object recognition, the computation of lightness, and binocular stereopsis. The concept of spatial frequency and the contrast sensitivity function are deftly introduced for the novice reader. The book is sumptuously and skilfully illustrated and the figures allow readers to experience for themselves many illusions and perceptual after-effects; indeed the author recounts in his preface how he originally set out to produce a collection of illusions for the general reader but, like a novelist taken over by his characters, was soon led to provide the intellectual background. Two-colour anaglyphs, many of them original, demonstrate phenomena of binocular vision. The major omission is a discussion of colour vision; this is odd, even inexcusable, given the lavish facilities available for colour illustration.

The exposition is one of almost unfaltering clarity and this is perhaps the most impressive quality of the book. If Frisby has any fault it is that of spelling points out too much — a virtue in a lecturer but a vice in an author; thus he devotes no less than ten, similar, figures to introducing the concept of a corner-detector.

In elaborating the computational approach to visual perception, Frisby acknowledges an explicit debt to D. Marr "whose writings are for me the work of genius". He discusses in detail, for example, Marr's theory of how the retina computes lightness, that is, discovers the reflectances of surfaces that are unevenly illuminated: bipolar cells detect edges by a centre-surround differencing operation; a threshold is applied to the resulting signal; and then (the "deconvolution" stage) lateral facilitation within one class of

ganglion cells causes all cells corresponding to points within a closed boundary to take on the lightness-signal indicated by the signal at the edge. Now, Marr's histological reification of this algorithm is, as Frisby says, "controversial" (to say the least), but there is a more general difficulty. The whole of Chapter 1 was devoted to disabusing the novice reader of a belief in the 'inner screen' theory of perception (the view sometimes called the Gestaltist fallacy); if our novice reader has taken that chapter to heart, then, when he reads Frisby's account of the computation of lightness, he will want to know why the visual system goes to such trouble to produce a picture of the scene in which lightnesses are redundantly represented in the interiors of homogeneous areas, why, that is, the deconvolution is necessary. And he won't be told.

Frisby leaves to a late stage in the book the details of retinal anatomy and physiology. Perhaps it is in this area that he is least sure of himself, for it is here alone

that errors occur in any density: in the course of two pages, the inner and outer synaptic layers are confounded, the pigment epithelium and choroid are labelled "sclera", rods are said to be 500 times more sensitive than cones because they contain rhodopsin, the fovea is said to contain only cones, an error of 10^3 is made in equating retinal extent to visual angle, and the amphibian mudpuppy (in a remark apparently lifted almost verbatim from Blakemore) is described as a fish. Undergraduates should be directed elsewhere for their retinal physiology.

The contributions of the editor, Henry Hardy, and the art director, David Warner, are so manifest in this book that their work deserves explicit congratulation. *Seeing* will be equally in place on the coffee table and on the first-year reading list. I strongly recommend it. □

J.D. Mollon is a Lecturer in Experimental Psychology at the University of Cambridge, UK.

Flawed search

Sara Champion

In Search of Ancient Astronomies. Edited by E.C. Krupp. Pp.277. (Chatto & Windus: London, 1980.) £8.95.

THIS book arose from a series of lectures given by the contributors in California in 1975, and is, according to its editor, "the first attempt to present systematically to the general reader the main results of archaeo-astronomy to date". It consists of seven chapters, four by the editor and one each by Professor Thom and his son, Dr John Eddy and Dr Anthony Aveni. It is clearly stated in Krupp's introduction that the "pseudoscientific misconceptions" of Erich von Däniken, Velikovsky and the like are to be "dispelled by the reliable, scientific findings of archaeo-astronomy"; it is unfortunate, therefore, that the majority of the chapters show some misuse or misunderstanding of archaeological data and imprecision in the demonstration of astronomical alignments.

The first chapter by Krupp himself is presented as a non-mathematical introduction to practical astronomy. This is necessary for the understanding of subsequent chapters, and is in general comprehensible, though some of the information could have been transmitted with fewer words and greater clarity.

For many readers the work of the Thoms will be the most familiar, and their chapter on stone circles and menhirs follows. Thom's eminence in the field is largely based on the accuracy of his measurements and the precision of his analysis. Recent papers and reviews have, however, cast doubt on some of his figures, with serious

results for his megalithic yard and megalithic calendar (Moir *et al.* *Antiquity* LIV, 37-43, 1980). Misidentification of archaeological monuments has resulted in Thom's describing hut circles and enclosures as stone circles of megalithic type, and some of the lines of foresight suggested for certain sites are shown in the field to be below horizon level, difficult to see without binoculars or blocked by natural features not obvious from maps. Some controversial sites appear in this chapter: the Crucuno Rectangle, for example, described by Thom as "lunar standstill alignments", is claimed by Daniel in *Antiquity* XLIX, 81, 1975, to be an AD eighteenth century folly. For the archaeologist prepared to be convinced, some of Thom's claims appear thin and several statements contentious. To be told that, at Rough Tor in Cornwall, many of the upright stones have fallen and the remaining ones do not adhere closely to the flattened circle design, perhaps because of solifluxion, begs the question — what flattened circle design is there left to be measured. Rules about the use of megalithic yards are stated, only for exceptions to be made immediately: "the sides of these triangles all had to be integers in megalithic yards", followed by "the builders discarded the rule that all radii must be integers".

The third chapter, by Krupp, deals with the work by archaeo-astronomers and others on the site of Stonehenge, several of whose papers have appeared in *Nature*. In general the treatment is descriptive rather than critical, which may be misleading for the general reader. Analysis of Hoyle's claim that Stonehenge was an eclipse predictor has been published by Moir (*Antiquity* LIII, 124-128, 1979); he points

M Introduction to NUCLEAR REACTIONS

G. R. SATCHLER

— Research staff member,
Oak Ridge National
Laboratory, Tennessee.

*Spring 1980; £25; 336pp;
ISBN 0 333 25907 6.*

Contents include — Some Background; Introduction to Nuclear Reactions; Elementary Scattering Theory; Models of Nuclear Reactions.

This book presents a summary of our present understanding of the Scattering and Reactions that occur in collisions between nuclei and is an introduction to the theoretical formalisms used to describe them. It is aimed primarily at readers in the undergraduate and beginning graduate student level but many others will also find it useful. The specialist from another field will find that this book is excellent background reading and the established nuclear physicist will find reading it to be helpful in refreshing the memory about areas in which he or she is not currently working.

out the problems of refraction, visibility, and variability in moonrise and moonset positions due to declination and perturbation which would affect the use of the site in this way. The same criticisms can be applied to Thom's work where it involves lunar observations. Again, the misuse of archaeology undermines attempts to prove alignments: Krupp's use of Figsbury Ring, at least 1,000 years later in date than Stonehenge, as a foresight for the southern major standstill moonrise, is inexcusable.

Eddy's chapter on North America is the only one in the book where a sensible caution appears. His balanced view of others' work is exemplified by his regard for the archaeology as equally important as the astronomy in the analysis of the Chaco Canyon structures. His own work on the Indian medicine wheels is a model of careful and logical procedure. The same cannot be said of Aveni's chapter on

Mesoamerica, where sites a millennium and several hundred miles apart are grouped on the basis of their similar orientation. The use in this chapter of words like "nearly", "close to" and "approximate" when describing alignments destroys their credibility. The claimed alignment of Teotihuacán on the setting of the Pleiades turns out to be "within 1 degree" of this event, a difference representing a sizeable slice of the horizon. Misunderstanding of archaeological data in this chapter results in Aveni using Flannery and Marcus' application of central place theory to Mayan settlements as evidence of geometrical and possibly astronomical location of these sites.

Krupp's chapter on Egyptian astronomy, mainly descriptive of previous work, is followed by his attempt to debunk von Däniken and the rest. His handling of the leyline controversy and the Glaston-

bury Zodiac lacks conviction, since he frequently ignores the most obvious line of attack; for example, he reproduces without comment the notorious leyline that runs from Stonehenge (third millennium BC) through Old Sarum (sixth century BC) to Salisbury Cathedral (AD twelfth century).

With the exception of Eddy's chapter, the book fails on its own terms, for it presents to the reader a picture based, in many cases, on misunderstood archaeological evidence and selective or imprecise numerical and astronomical data. The non-expert may unfortunately be persuaded by the jaunty air and punning subheadings (e.g. "A Serious Mystery" for a section on Sirius) into believing it all. □

J. Z. Fullmer

Benjamin Thompson, Count Rumford. By Sanborn C. Brown. Pp.576. (MIT Press: Cambridge, Massachusetts, and London, UK, 1979.) \$19.95, £12.40.

BENJAMIN Thompson, born in March 1753 in Woburn, Massachusetts, died Benjamin Thompson, Count Rumford, in August 1814, in Auteuil, France. By almost any criteria his biography should make a rattling good yarn, for his adventurous life had episodes of intrigue, of mystery and of passion. He promoted large scale social experimentation and technological innovation; he interpreted his scientific experiments in ways that propelled him into controversy with the conservative members of the scientific community. When young and a volunteer member of the American army he functioned as a Royalist spy. In the spring of 1776, he fled to England, where he promptly ingratiated himself with influential British government officials. In 1783 he went to the Continent, becoming an agent for the British in Munich (or, perhaps, a double agent — the record is cloudy). Subsequently he shuttled back and forth between England, Ireland and Europe with no apparent regularity or design, his movements dictated by opportunity. He acknowledged two illegitimate children, one in Munich, the other in Paris, and sired one legitimate child, Sarah, born in Massachusetts. Assured that his abandoned American wife was truly dead, he married Jeanette Lavoisier (*née* Paulze), Antoine Lavoisier's widow, from whom he was soon divorced after a series of spectacular and public brawls. Moreover, during long

periods in England and on the Continent he associated closely with well-placed reputed homosexuals, furthering his own career through these connections.

He managed to be close to centres of power in the government circles to which he propelled himself, and in the international scientific community. In 1780 he was elected Fellow of the Royal Society — he was 27 — after having attracted favourable notice for his very long paper on the nature of heat. For nearly a decade he earned the attention of Karl Theodore, the Elector of Bavaria, to whom Rumford owed his honorary title. The scientifically conservative Napoleon showered attention on him, and in England Sir Joseph Banks, PRS, abetted some of his plans. Rumford published a large number of papers: on the nature of heat

and of light; on the best designs for stoves; on ways to feed the poor; on the efficient use of fuels in kitchens and fireplaces; on the boring of cannon; and on a pot for brewing coffee. He laid out the English Gardens in Munich; he devised plans to reduce beggary in Bavaria while feeding and clothing the army; he promoted the erection of a technological museum that offered visitors 'hands-on' experiences; he attempted to educate artisans in the factory ways of the industrial revolution; together with Banks he founded the justly famed Royal Institution of Great Britain.

Yet even this extensive listing of his promotional efforts does not exhaust them. While still alive Rumford proffered sums of money to England and America, endowing the prizes known as the Rumford Medals of the Royal Society and of the

Demonstration lecture by Thomas Young and Humphry Davy, with Count Rumford watching.

American Academy of Sciences. Instructions in his will established from the residue of his estate the "Rumford Professor of the Physical and Mathematical Sciences as applied to the useful Arts" at Harvard. These eponymous memorials furthered his imprint on the scientific community. Perhaps Rumford was not unique, for adventurers of all sorts abounded in revolutionary times. Moreover, the history of technology provides us with occasional examples of scoundrels — but Rumford must be unique in the degree of his rascality. He appears to have been a man devoid of real allegiances, clever enough to exploit the political turmoil and the scientific conceptual turbulence of his times for his own good.

Sanborn C. Brown, Emeritus Professor of Physics at MIT, presents the fruits of nearly 40 years of search for the original documents relating to Rumford's career. For these efforts every subsequent scholar will be grateful. In 1962 Brown wrote *Count Rumford Physicist Extraordinary*, one of the publications in the Science Study Series, which related in a chronological way what he had learned of Rumford's life. Brown's new biography expands upon that earlier book without deviating from its patiently explanatory tone and linear structure.

Brown, of course, has not been alone in paying attention to Rumford's life and accomplishments. Many historians of science, historians of technology and sociologists of science have examined portions of Rumford's activities, and it is to the neglect of this informing and analytical literature that Brown's biography owes its greatest weakness. Examples are not difficult to come by. Robert Fox in *The Caloric Theory of Gases* (Oxford University Press, 1971) has examined Rumford's work on the nature of heat, and placed Rumford's ideas within their contemporary milieu. Although Brown cited Fox's work, he did not use it to inform his own discussion. Morris Berman has analysed the early days of the Royal Institution in *Social Change and Scientific Organization: The Royal Institution, 1799–1844* (Cornell University Press, 1978). While Berman's general interpretation and analysis is the subject of considerable debate, much of what he has said is both useful and informative to the biography of Rumford. Brown appears to have been unaware of Berman's contributions.

Reading the biography of any practising scientist (even a part-time scientist, as Rumford assuredly was) raises the question: what is the most important aspect of such biography? To be sure, the biographer owes his subject as accurate a chronicle of the chief events in the life as can be achieved. Brown has provided that for Rumford. But the biographer of a scientist also owes his reader the benefits of his analysis of the subject's endeavours, of his achievements as seen by his

contemporaries, of his failures as judged by his contemporaries, and an assessment of where the subject fits into the histories of science and of technology. While Brown discusses Rumford's work on the nature of heat chronologically, he has not truly shown what motivated Thompson's extensive experiments. What is missing is the deep analysis which a historical study requires. When Brown discusses Thompson's social reforms he chronicles the major efforts, but he fails to show whether Thompson regarded his projects as intellectual solutions to complicated puzzles, as palliatives to grievous human needs or as a means for currying personal favour for himself. Above all, Brown does not appear to have realized how much of an outsider Count Rumford was; the narrative suggests that Rumford functioned at his best only when he enjoyed a perverse, self-engendered alienation. Perhaps, in this instance, the abiding question should have been "What made Rumford run?"

Thomas Gainsborough's portrait of Colonel Thompson at the age of 30.

Physicists publishing research findings must do more than offer raw data. Generally, that data has to be placed within a larger conceptual framework. The historian and the biographer have the same obligation. To view a man as a two-dimensional cardboard cut-out (no matter how colourful), jerked into spasmodic action by unseen wires and strings against a flat backdrop, impoverishes our understanding of him. It is on this score that Brown's biography of Rumford is most disappointing. Brown's biography is not the definitive life of Rumford, but it does offer a brave factual beginning on which subsequent analysis must rely. □

Of special concern

Austen Albu

Science and Technology: A Five-Year Outlook. By the National Academy of Sciences. Pp.544. (Freeman: San Francisco and Oxford, 1980.) Hardback £8.90; paperback £5.40.

IN 1977 the United States Congress legislated for a periodical Five-Year Outlook on Science and Technology. The responsibility for this work was eventually transferred to the National Science Foundation. In 1978 the Foundation asked the National Academy of Sciences to prepare a report describing the current state of significant research areas and pointing out those areas which would be of special concern within the five year period. A review procedure by members of a number of other bodies was established. Those involved included 50 contributors, 20 editorial consultants, and 170 reviewers and additional contributors. Although the resulting report is by no means comprehensive and only intended as a preliminary study, it covers a number of fields in encyclopaedic fashion and one can only express admiring astonishment that it should have been produced by March 1979.

British Members of Parliament have long envied the resources available to their American colleagues and, for all their growing interest in science and technology during the past few years, they would never have succeeded in commissioning a report on this scale. Written in a straightforward style, not over-popularized, it offers descriptions of recent and likely future developments in such fields as geology, biology and biochemistry, physics, computers, energy, and US demography and health. Some of the subjects are politically sensitive and tend to be dealt with in a rather didactic manner; but on the whole the problems requiring research in the near future seem to have been set out fairly. Of course neither the average congressman nor this reviewer is capable of judging the scientific quality of these descriptions and proposals, and the problem of choice of priorities remains as difficult as ever. I am reminded of a remark of my son's when, in his twenties, he was facing a choice in his life on which he had consulted his liberal parents: "Just like my parents, tell me all the pros and cons and leave the decision to me".

Two criticisms can be made of this report: there are no price tags attached to any proposals for the future, without which serious consideration of alternatives by a legislative body is impossible. Perhaps equally serious is the lack of any reference to Defence R&D, the cost of which overshadows all the rest and which itself

contributes indirectly to so many other fields.

The problems now facing American scientists and engineers, though vastly greater in scale, are common in advanced industrial countries. There has been a collapse of the academic boom of the 50s and 60s. Average annual growth at constant prices of funding for academic R&D from 1953 to 1960 was 12%; from 1960 to 1964, 14%; from 1968 to 1974, zero; and from 1974 to 1978, about 4%. Despite increased numbers of graduate students, doctorates in science and engineering are declining. Total support for basic academic research declined by 8% between 1968 and 1976 and federal support by 10%.

Naturally the overwhelming number of developments reported are concerned with

practical and, in some cases, urgent problems: energy, material resources and health. Their solution is difficult enough in scientific terms but is increasingly hindered by social and political considerations. These are not only panic reactions as in the case of genetic manipulation or nuclear energy after Harrisburg but arise out of growing concern with environmental questions, leading to regulatory procedures. No doubt there is some special pleading here. Even the possibility of expanding the use of coal is hindered by the opposition of agrarian states to its mining in their territories and by fear of the atmospheric effects of its use in power stations. For this reason conservation is priority number one in the energy field. Of course vested interests are involved and indications of these can be detected in some

of the reports. Political decisions can also distort the allocation of R&D resources, tactfully referred to in an account of the examination by "a new leadership" of the "enormous effort" of Nixon's "War on Cancer" in order to achieve a more balanced programme.

Many readers of this fascinating book must be left with two impressions: the enormous area remaining for scientific R&D to deal with the world's material problems and search for knowledge; and, in a divided world, the considerable international cooperation here reported and the need and scope for its further enlargement. □

Austen Albu was a Member of Parliament from 1948 to 1974, and a Visiting Research Fellow of the University of Sussex Science Policy Unit, Brighton, UK, from 1975 to 1979.

Bringing Man poetically to life

Yves Coppens

The People of the Lake: Man, His Origins, Nature and Future. By Richard E. Leakey and Roger Lewin. Pp.223. (Collins: London; Doubleday: New York, 1979.) £6.50.

People of the Lake is a kind of essay on Man. Pleasantly readable, it puts forward in a little over 200 pages an overall view of our species in both a historical and comparative context which is thoroughly satisfying for anyone with a naturalist's turn of mind. Although the reader may regret a certain lack of rigour in the comparative approach, as too great an emphasis is placed on seeking out good examples to back up the argument at the expense of a critical attitude towards similarities and differences, the attempt is nevertheless an extremely interesting one, and one worthy of being encouraged.

Divided into 11 chapters, the book is in fact made up of two sections of almost equal length; the first of these, comprising the first five chapters and part of the eleventh, is devoted to palaeontology, the origin and evolution of Man, from the first primates of 70 Myr ago to *Homo sapiens sapiens*; the second (Chapters 6, 7, 8, 9, 10 and the remainder of Chapter 11) concerns itself with ethology, human behaviour and the search within the animal kingdom for Man's origins and the direction of his evolution. Given the training and special interests of the authors, this second part is more an essay in prehistoric ethology: just like chimpanzees, gorillas, baboons or geladas, contemporary Man is used in an attempt to reconstruct the lifestyle, psychology and behaviour of ancient Man. In spite of what

might be inferred from the sub-title, neither the future of mankind, nor even his present condition, seem to be the writers' principal concern.

The point of departure — hence the title — is the palaeontological research carried out by Richard Leakey over the past 12 years on the shores of Lake Turkana in Kenya. In 1967, Richard Leakey, together with Francis Clark Howell and myself — and initially Louis Leakey, his father, and Camille Arambourg — played a part in setting up the important international expedition along the Omo River in Ethiopia, to the north of Lake Turkana itself; and it was during one of the many flights that had to be made back and forth between Nairobi and his camp on the Omo that he noticed the sedimentary formations outcropping on the eastern banks of the lake. He decided there and then to investigate, and since 1968 a dozen or so separate expeditions have provided an extraordinary collection of human fossils, their age ranging from more than 4 Myr to less than 1 Myr and including half a dozen skulls in an excellent state of preservation, highlighted by the famous ER-KNM 406 (*Australopithecus boisei*), 1470 (*Homo habilis*) and 3733 (*Homo erectus*). These expeditions, known as the Koobi Fora Project, make up one of the four large-scale international projects under way in the Rift Valley of East Africa and concerned with the problems surrounding the origin of Man. The other three are the Olduvai expedition (more recently Olduvai-Laetoli), originating with Louis Leakey as long ago as 1931 and under the direction initially of Louis Leakey, then of Louis and Mary Leakey and, since Louis' death in 1972, of Mary Leakey alone; the international Omo expedition for which Francis Clark Howell and myself were responsible over eight further seasons after the departure of Richard Leakey in 1968; and the Afar international expedition, which began work in 1972 and has since been under the supervision of Maurice

Taieb, Donald Johanson and myself. The People of the Lake themselves, of course, are these fossil men of about 2 Myr ago (*Australopithecus boisei* and *Homo habilis*), whom the authors bring poetically to life again as early as the first chapter of the book, in a reconstructed landscape on the banks of a palaeolithic Lake Turkana.

The palaeontological résumé provided is rather conventional but not without interest. It traces the links between Cretaceous and Quaternary forms, the change from a nocturnal to diurnal life (and the consequent improvement in eyesight), and, much nearer in time to ourselves, the straightening up of the body and its probable successive implications — the freeing of the hands, work, development of the sweat glands, loss of hair and the appearance of a protective pigmentation for the body. Considerable passages of the book are devoted to this possible ancestor of Man, the quadruped *Ramapithecus*, and his erect descendant the *Australopithecus*, and to the irritating gap of 4 Myr that separates them.

The ethological aspects examined in the second section of the book represent in many cases interesting approaches to problems which are not usually dealt with in the context of prehistory. They all arrive at the same fundamental conclusion: that Man is as he is because at the time of his origin he shared his food with the other people in his group — the development of his intelligence (and of his language, which is no more than a manifestation of his intelligence), the extraordinary transformation of his technology, his inclination for reciprocal altruism and for family life, even his obsession with sex — are the fruits of his cooperative life and of his mixed economy based on the male's hunting and the female's gathering: everyone is in part dependent on others. With this idea established as their foundation, the authors go on to debate a wide range of problems raised, rightly or wrongly, by our times, or by other writers whose success has

moulded our view of our times: the hypothesis of the essential role of hunting in the evolution of Man, the counter-hypothesis of the preponderant role of gathering, the problem of Women's Liberation, the still unsettled question of the origin of aggression and of the phenomenon of war, and so on.

It is unfortunate that these topics are touched on only rather superficially, though it could scarcely be otherwise in such a limited space; from this point of view it must be admitted that the reader's appetite is never entirely satisfied: he is left not wholly convinced by an argument too fragmentary in its evidence. Nonetheless, the very fact that some additional light has been thrown on all these various problems by authors possessing zoological, ethological, prehistorical, palaeontological and ethnological knowledge, obviously deserves a salute. Indeed, a second salute, as I have already stressed the importance of a comparative approach in the introduction to the French edition of the present authors' earlier work *Origins* (for a review, see *Nature* 270, 108; 1977).

Nevertheless, I cannot agree with every statement made in this book. It may be instructive to look at some of the points of disagreement. On page 73, the *Australopithecus* is introduced to us as a possible herbivore although there is little likelihood that it can actually have been one; he was in fact not sufficiently far removed from Man to have had a fundamentally different digestive apparatus. And Man is incapable of digesting cellulose.

Between 1955 and 1960, Johannes Hürzeler, in connection with his study of the *Oreopithecus*, pointed out the great antiquity of the phenomenon of bipedality in nature. A demonstration (page 70) of the existence of bipedality only 4 Myr ago is not therefore going to come as much of a surprise to vertebrate palaeontologists, who for the past twenty years have been expecting to uncover its existence in the Miocene.

The notion (page 131) that the brain was among the first organs to take on human form, rather than the contrary suggestion, has long prevailed; hence, the celebrated Piltdown hoax of a fossil man with a modern brain and pongid teeth. And when authentic and extremely ancient fossils, such as the first Taung *Australopithecus* skull, have been brought to light, it has been quickly established that the brain, although of modest development, was different from that of the great apes.

One should not confuse (page 92) written knowledge with the knowledge of nature that can be acquired in the field; any farm worker in any Western country, living in close contact with his surroundings and often hunting game there, would surprise Richard Leakey and Roger Lewin with the quality and diversity of his knowledge of the fauna and flora, even of the very rocks, of the countryside about him.

How is it possible (page 126), in a work

which (rightly) attempts to demonstrate the precarious nature of the borderline between the apes and Man, in respect of the use (and manufacture) of tools and the notion of natural facing elements (the rain dance of the chimpanzees, for instance), to come out with a statement as specific as "we suggest that it was primitive *Homo* . . . who made tools and, furthermore, that it was only *Homo* who did so"? Why is it not possible that the *Australopithecines* may have made a beginning which Man inherited and then developed brilliantly? Linking the tool so dogmatically to the genus *Homo*, the authors throw the definition of the genus into confusion — a definition which should remain strictly biological.

May I finally be permitted to give vent to my irritation at the habit, not at all international in spirit, of expressing all measurements in inches, feet, yards, miles and square miles; in 1980 we are all citizens of the world!

These differences are, it need hardly be said, extremely minor in the context of an overall impression of a highly intelligent work, which has the great merit of linking natural sciences and the humanities.

Let me now turn from these basic issues to make a few remarks on form. As I pointed out at the beginning of this analysis, this is certainly an admirably

readable book. It is made so by its style, and by an approach which, though scientific, is always deductive. It is enlivened by the use of entertaining asides, such as anecdotes like those describing how Tom Gray and Donald Johanson discovered Lucy, the context in which Ralph Holloway studied his endocranial casts, or the anxious cleaning of skull 3733 by Alan Walker; and, not least, by the interrogative way which they sometimes use to outline the problems better; the questions asked are precisely those the reader is likely to be asking himself.

We learn by this book that Man is very ancient; his origins, both morphological and behavioural, have deep roots in the animal kingdom. It is by studying this kingdom and systematically analysing all contemporary human societies that we may come up with the answers to questions about our own origins, the process of our evolution and, consequently, to some limited extent, about our future. It is only through a better knowledge of our past and of all that can illuminate it that we may come to be able to foresee, and forestall, our destiny. □

Yves Coppens is Co-Director of the Omo and Afar international expeditions, and Deputy Director of the Musée de l'Homme, Paris.

Richard Leakey examines a hominid jaw while seated on the dry bed of a seasonal stream.

The Evolution of the Igneous Rocks

Fiftieth Anniversary Perspectives
Edited by H.S. YODER, JR.

"Historians of science should have a good time with this book and with Bowen. Having the master's book brought up to date by his able followers is in itself a rare experiment, particularly when preceded by such an explosion of discovery. That such a format could even be contemplated is impressive testimony to the prophetic integrity of the original. That it should succeed is a modest triumph of common purpose and good sense."

A must for all plant physiologists – by internationally recognized experts

Encyclopedia of Plant Physiology

New Series · Editors: A. Pirson, M.H. Zimmermann

VOLUME 1

Transport in Plants I

Phloem Transport

Editors: M. H. Zimmermann, J. A. Milburn

"...Of the several excellent books that have been published on this subject over the last several years, this book is by far the best. One must not read just one chapter to obtain a balanced view of a given topic, for each author has written from a specific intellectual stance, allowing a balanced view to be presented by the entire book. This has the advantage that each chapter is very readable, since it is not structured as a review article... Since all points of view are presented and this book covers the subject completely, it is doubtful that another book on carbohydrate translocation will be published until significant additional advances are made in this field."

Bio Science

1975. 93 figs. XIX, 535 pages. Cloth DM 158,-; approx. US \$ 93.30
ISBN 3-540-07314-0

VOLUME 2

Transport in Plants II

Part A: Cells

Part B: Tissues and Organs

Editors: U. Lüttge, M. G. Pitman

"... This publication is an excellent review work which will prove invaluable to research workers in the field of solute transport. Many of the articles are suitable for undergraduate teaching... The volume is very well produced with figures and plates of adequate size for easy comprehension. Both parts are provided with an author and subject index, and lists of symbols, units and abbreviations."

The New Phytologist

A: 1976. 97 figs., 64 tables. XVI, 419 pages
Cloth DM 128,-; approx. US \$ 75.60
ISBN 3-540-07452-X

B: 1976. 129 figs., 45 tables. XII, 475 pages
Cloth DM 138,-; approx. US \$ 81.50
ISBN 3-540-07453-8

VOLUME 3

Transport in Plants III

Intracellular Interactions and Transport Processes

Editors: C. R. Stocking, U. Heber

"... This third multi-author volume is concerned with intracellular interactions and transport processes, a topic of considerable current interest... it will serve as a useful summary of progress to date and as an indicator for future research... The book is well illustrated and

contains a thorough author and subject index... lives up to the high standards set by the preceding numbers in this series." *Nature*

"... a readable and useful volume... with an excellent perspective... Clearly presents both existing knowledge and uncertainties... Provides an excellent critical analysis of the subject... [that is] valuable for informing the reader so well..." *The Quarterly Review of Biology*

1976. 123 figs. XXII, 517 pages
Cloth DM 145,-; approx. US \$ 85.60
ISBN 3-540-07818-5

VOLUME 4

Physiological Plant Pathology

Editors: R. Heitefuss, P. H. Williams

"... 33 individual articles covering a wide range of topics... are all by well known investigators... a highly specialized review... readers who are interested in the subject of physiological plant pathology will find the volume a convenient place to go..."

The Quarterly Review of Biology

1976. 92 figs. XX, 890 pages. Cloth DM 194,-; approx. US \$ 114.50
ISBN 3-540-07557-7

VOLUME 5

Photosynthesis I

Photosynthetic Electron Transport and Photophosphorylation

Editors: A. Trebst, M. Avron

"This excellent reference and source book contains 42 articles... written by active research workers... An impressive amount of new knowledge has been acquired about these subjects in the past fifteen years, and this is well summarized through 1975..." *Amer. Scientist*

"... This goal has been admittedly achieved by the two editors of the book, Trebst and Avron who both are not only experts in the field of photosynthesis but also have considerable editing experience... The volume is certainly not "just" another book on photosynthesis but in its kind a unique accomplishment in the attempt to evaluate and order on a reasonable number of pages the unbelievable amount of information that has accumulated over the past 20 years. The editors have certainly done an excellent job."

Z. Pflanzenphysiologie

"... The standard of writing and presentation is uniformly high... This volume has much to commend it, not least the excellent indices... It is clear this will remain a major work of reference for many years to come..."

Phytochemistry

1977. 128 figs. XXIV, 730 pages. Cloth DM 199,-; approx. US \$ 117.50
ISBN 3-540-07962-9

VOLUME 6

Photosynthesis II

Photosynthetic Carbon Metabolism and Related Processes

Editors: M. Gibbs, E. Latzko

This book examines the mechanism and regulation of photosynthetic CO₂ fixation and related carbon metabolism, as well as those parts of hydrogen, nitrogen, and sulfur metabolism that are closely connected to photosynthesis. Information on the Calvin-cycle of CO₂ fixation, and on C₄ metabolism in C₄ plants and plants with crassulacean acid metabolism is presented from studies using whole tissues, isolated cells and isolated chloroplasts. Interactions between photosynthesis, respiration, and photorespiration are described, and the metabolism of starch and sucrose is examined. A section on the enzymes of the Calvin-cycle and C₄ metabolism includes an introduction to enzyme regulation.

1979. 75 figs., 27 tab. XX, 578 pages. Cloth DM 198,-; approx. US \$ 116.90
ISBN 3-540-09288-9

VOLUME 7

Physiology of Movements

Editors: W. Haupt, M. E. Feinleib

Plant movements cover a wide field of plant physiology. This volume emphasizes those fields where substantial progress in understanding has been made, or where major new aspects are evolving. It is devoted particularly to the mechanisms of perception, transduction and response common to completely diverse types of movement. On the other hand, these steps of the reaction chain may be different even within a given type of movement for different examples. This volume clarifies and analyzes the signal chains that lead to movements in plants.

1979. 185 figs., 19 tab. XVII, 731 pages
Cloth DM 198,-; approx. US \$ 116.90
ISBN 3-540-08776-1

VOLUME 8

Secondary Plant Products

Editors: E. A. Bell, B. V. Charlwood

The first comprehensive exposition of this important and timely field, illuminates recent research results on a variety of secondary plant by-products. Using numerous illustrations and tables, Drs. Bell and Charlwood discuss the biochemical and physiological phenomena involved in the synthesis and accumulation of compounds such as alkaloids, isoprenoids, plant phenolics, non-protein amino acids, amines, cyanogenic glycosides, glucosinolates, and betalains. **Secondary Plant Products** is sure to become a standard reference to all botanists, biochemists, pharmacologists, and pharmaceutical chemists.

1980. 176 figs., 44 tab. and numerous schemes and formulas.
XVI, 674 pages. Cloth DM 198,-; approx. US \$ 116.90

OTHER WORLDS

Space, Superspace and the Quantum Universe

PAUL DAVIES

There could be an edge to time at which the whole universe might disappear for good
Alternative worlds overlap our perceived universe and jostle its atoms
Time does not pass nor does there exist a past, present and future

In the follow-up to his successful *The Runaway Universe*, Paul Davies argues that other universes could have been selected and may even exist in parallel with our own or in remote regions of spacetime. Never before has the quantum theory of the universe been so cogently argued and so lucidly presented, clearly demonstrating that our traditional understanding of 'reality' must be overthrown.

International Journal of COAL GEOLOGY

Editor-in-Chief: W. SPACKMAN,
Pennsylvania State University

An increasingly large amount of research, both theoretical and applied, is being carried out in the field of coal geology but, until now, no specific journal has been able to offer a suitable platform for the publication of the results of this work. This is rectified with the launch of Coal Geology which will undoubtedly become a valuable source of information for all those working in the field. Coal Geology is an international journal committed to treating the basic and applied aspects of the geology and petrology of coal in a scholarly manner.

Its scope encompasses: the genesis of coal and coal seams, including studies of modern coal-forming processes and environments; the metamorphosis of coal materials in coal seams and dispersed in other rock types; the geology of coal measures including stratigraphic, structural, geomorphic, paleogeographic, paleoecologic, hydrogeologic, palynologic, paleozoologic and paleobotanic facets of the subject; the petrology and petrography of coal and coal seams including coal mineralogy, geochemistry and the chemical and physical constitution of coal.

Oceanographic laboratories

A. S. Laughton

Oceanographic Institutions — Science Studies the Sea. By P. Limburg. Pp.265. (Elsevier/Nelson Books: New York, 1979.) \$9.95.

THE public image of a scientific laboratory and of the scientists who work in one is highly coloured by what is seen on television and by science fiction. It is therefore very valuable for a book to be published which explores the reality of research institutes and attempts to look at the motivation and day-to-day working of research scientists. By choosing a subject such as oceanography which has grown rapidly during the past three decades, but the roots of which go back to the last century, it is possible to relate the development of the science with the development of the laboratories studying it.

Limburg has written a book that tackles with varying success both the science and

the laboratories. As a potted history of oceanography his first three chapters leave a good deal to be desired. There are inaccuracies (the first word in the acronym ASDIC is "Allied" not "Anti-"), a lack of understanding of some of the technology (the difference between reflection and refraction seismics) and a rather journalistic view of the development of scientific thought (from continental drift through stable continents towards plate tectonics). The historical review is very unbalanced. Two pages are devoted to diving and subsea habitats, whereas deep-sea drilling is limited to 11 lines, and oceanography from space to six. Near-bottom technology scarcely gets a mention nor do the achievements of long-term deployments of instruments in the ocean, which depend crucially on the developments of marine acoustics.

The accounts given of the work in the major (and some minor) oceanographic laboratories in the USA are both informative and interesting, and the unravelling of the complexities of US Government agencies' funding of ocean research is revealing, if perhaps somewhat

ephemeral. As the book proceeds, it becomes clearer and clearer that the author is really concerned with oceanography in the USA and I wonder why this was not made clearer in the title. Oceanography in all other countries is limited to one chapter and appears to include only those laboratories which the author was able to visit. No mention at all is made of oceanographic institutions in the USSR or in Japan. It cannot therefore be said, nor is it claimed in the Introduction, that the book is a comprehensive review of oceanographic institutions. What it does provide, and in this is its success, is a peep in through the doors of some of the laboratories, an insight into the enthusiasm and motivation of some oceanographers both great and small, and an indication of the breadth of the subjects studied.

For a student wishing to start a career in oceanography, especially in the USA, I warmly recommend this book. □

A. S. Laughton, Director of the Institute of Oceanographic Sciences of NERC, has spent his working life in the field of marine geophysics, and has worked closely with several of the major oceanographic institutions in the USA.

The wonder of it all

R.H. Dalitz

Knowledge and Wonder: The Natural World as Man Knows It. Second edition. By Victor F. Weisskopf. Pp.312. (MIT Press: Cambridge, Massachusetts, and London, UK, 1980.) Hardback \$15, £9.30; paperback \$5.90, £3.70.

TODAY we have knowledge of our Universe covering distances from 10^{-16} cm to 10^{+28} cm, and for time intervals from 10^{-24} s to 10^{+17} s. All the phenomena observed within these limits are apparently governed by a very limited number of physical forces. The aim of this book is to lead non-scientists to appreciate the wonder of this situation, first by indicating simply how we know the facts and then by illustrating the wide variety of phenomena governed by these forces. Such an endeavour necessarily involves some oversimplifications, of course. Here the job is done in low key, showing how simple concepts based on the laws governing these forces can lead to an understanding of this strikingly wide variety of phenomena.

The book begins with space and time. It estimates the lifetimes of Earth and of the Universe, and the sizes and distances in the visible Universe. Two major forces are obvious to us from daily life, gravitation and electromagnetism. Their characteristics are outlined and related to the variety of phenomena to which they give rise. We

explore the Solar System, understand the Milky Way as our galaxy, and relate it with far-off galaxies, made visible by telescopes. On Earth, we explore the structure of the atom and learn of its tiny nucleus, first deduced from Rutherford's alpha-particle scattering experiments. Both electrons and light show both particle and wave characteristics, and we soon reach quantum mechanics, with discrete energy levels for atoms, each level corresponding to a standing wave of electrons circulating about its atomic nucleus. The Coulomb force accounts for the binding of these circulating electrons to the nucleus, and also for the forces between atoms. We are shown the most common bonding mechanisms between atoms, and use the atoms as building blocks to make molecules, crystals and other solids and liquids, and so account for the materials around us as due to electromagnetic forces.

Next we are led to still shorter distances, to the nuclear and subnuclear worlds. The atomic nucleus consists of protons and neutrons, bound together by strong nuclear forces, and we soon understand why the stable nuclei are limited in number. An atom's chemistry then depends primarily on the proton number of its nucleus, and a pure chemical element can have various atomic mass values, corresponding to the number of neutrons in its nucleus. The ancient dream of transmuting other elements into gold is now seen to be possible, although so expensive that it has no financial value.

Recent experiments on the scattering of electrons and neutrinos by nuclei have shown that the nucleons themselves are

composite, each containing three quarks. The rich spectroscopies of atoms and nuclei, each due to their multiplicity of component particles, are now paralleled by a spectroscopy of nucleons, due to excitation of the motions and spins of their component quarks. These experiments also show us that quarks, as well as electrons and neutrinos, have no detectable structure larger than 10^{-16} cm.

We turn now to our terrestrial environment. Earth's long history is traced out, great changes occurring in its surface structure long before Man's emergence in recognizable form through evolutionary development. Thus, we come to the story of Life itself. The great steps are traced out, although not in detail, for we do not know them. We understand how the basic molecules needed to make up living material could form, perhaps through lightning flashes on the Earth's surface. The energy falling on Earth from the Sun was essential for the subsequent development of more complex organisms. Earth became covered in green, due to the chlorophyll which uses the energy reaching us from the Sun so efficiently. In the course of time, more complex organisms evolved, their structure being determined by the double-stranded DNA molecule, a thread carrying instructions for the construction of a living being, a thread replicated in its every cell. This evolution from simple to complex organisms, to living beings and to *Homo sapiens*, cannot be traced in detail but the general principles are outlined. The important role of mutations in this development is emphasized, and we see how the life on earth today could plausibly have

resulted from such an evolutionary history. Finally, we recognize that evolution in Man's behaviour has become rapid relative to his lifetime, since mankind now gains new knowledge quickly and disseminates it efficiently, so that new situations for humanity can now develop in the space of years. This evolution is of a new kind, not concerned with Man's structure but with his ability to control and change his environment. It is still quite unclear where this new evolution may lead us.

This story is recounted in simple terms, with compelling logic. The original lectures were for a high-school audience, and this extended version is still suitable for them. But it has much interest for all, and I hope that it will become more widely known. It could perhaps be simplified more, or extended in several places where questions are left unanswered. The book will be valuable for scientists, since few are familiar with all of the areas covered. The presentation is stronger and more tightly argued in the earlier chapters concerned with chemistry and physics than in the chapters concerning Life, where the author's knowledge comes from other scientists. The story of Life is much more complicated than that of inorganic matter, and can only be outlined in such a short space.

Each reader will have his own short-list of significant topics not covered in this book. For example, the uniqueness of our situation on Earth might have been underlined by a brief comparison of Venus with Earth; why have two planets of such similar constitution, mass, and so on, turned out to be so different today. Again, neutron stars are well known now, some of them as pulsars, of which there are many in the sky, but they are not mentioned; nor are quasars nor black holes, but these are not yet understood and they lie on the edge of Einstein's gravitational theory, which the author consciously chose to omit. At the other extreme, the book gives no hint of the complexity of the quark world; we know 15 kinds of quark today, and other fundamental entities are also needed. There is no mention of the weak-decay interactions, the unification of which with electromagnetism to form 'the electroweak interaction' has been such a major theoretical triumph recently. Such topics would perhaps complicate the story without adding much enlightenment, but still they are part of our everyday world. Even the strange particles are being formed around us by the cosmic radiation incident on Earth, although they quickly decay, and this cosmic radiation can be made visible with simple equipment which can be constructed in any home; it is part of our environment. Perhaps the book should have a few appendices, which could take the interested reader further towards the extreme boundaries of present research. I found few errors in the book, but it is stated on p.179 that the highest energy accelerator today, producing proton beams up to 500

GeV, is in operation at the Brookhaven National Laboratory, Long Island; it is actually at the Fermi Laboratory, near Chicago. It also puzzled me that more than half a page should be devoted to the outmoded 'continuous creation' theory of the expanding Universe, definitely excluded by observation for some time past.

In conclusion, I can only say that this book is superb and far ahead of any other global accounting of our Universe, in both the large and the small. We all have friends and relatives who question us often about

modern science; this is the book to place in their hands. It shows the physicist at his best, accounting for what he sees by simple order-of-magnitude estimates. The story of Life is less amenable to this approach, and so those chapters are more descriptive. However, as it now is, the book already satisfies a great contemporary need. □

R. H. Dalitz is Royal Society Research Professor in the Department of Theoretical Physics at the University of Oxford, UK.

Star maps, old and new

David W. Hughes

The Sky Explored: Celestial Cartography, 1500-1800. By D. J. Warner. Pp.293. (Alan R. Liss: New York; Theatrum Orbis Terrarum: Amsterdam, 1979.) \$70. *True Visual Magnitude Photographic Star Atlas.* By C. Papadopoulos. (Pergamon: Oxford and New York.) Three volumes. Vol.1. *Southern Stars*, 1979; £100, \$225. Vol.2. *Equatorial Stars*, 1979; £145, \$325. Vol.3 *Northern Stars* (by C. Papadopoulos and C. Scovill) publication due June 1980.

SINCE the dawn of history, mankind has been a fascinated observer of the heavens. The stars were arranged into groups of constellations and names were given to these constellations and also to many of the brighter stars. However, without a good celestial map the night sky simply dissolved into a trackless confusion of points of light. Maps were also a simple means of recording the knowledge gleaned from celestial observations. In the old days the constellations were depicted by artistic, symbolic figures, and many of the early star maps and globes became much more than just scientific aids but were also beautiful works of art in their own right.

The first important extant star catalogue was compiled by Ptolemy in AD 150 and contained 1025 stars grouped into 48 constellations. Ptolemy's work was the cornerstone of mediaeval star catalogues and, for more than 1,400 years, Islamic and European astronomers limited their observations to the stars listed by Ptolemy. The catalogue of Al-Sufi in the tenth century, Ulugh Beg's Alfonsine Tables in the fifteenth century and the Copernicus catalogue in the early sixteenth century were simply revisions of Ptolemy. These catalogues were usually just lists of stellar latitudes, longitudes and magnitudes.

Most astronomers found that a graphic form was more useful than a catalogue, and so maps of the sky were introduced. The first flat star map of any significance was published by Albrecht Dürer, the great Nuremberg artist and mathematician, in

1515. The date reflects both the development of printing and the upsurge in the study of astronomy initiated by such worthies as Copernicus, Regiomontanus and Piccolomini. The era of great celestial cartography probably ends with the publication of John Elert Bode's *Uranographia* in 1801. Bode used 99 constellations and included 17,240 stars down to eighth magnitude. After Bode the constellation boundaries became more rational, the constellation figures slowly disappeared and star maps lost much of their charm and beauty becoming the dull procession of differing sized dots we know today.

Deborah J. Warner, the curator of the History of Astronomy at the National Museum of History and Technology, Smithsonian Institution, has produced a comprehensive catalogue of all the flat star maps printed in Europe between the fifteenth and early nineteenth centuries. Also included are details of a few globes for comparison. It is a work of considerable scholarship and, as a source of detailed information, will be a much valued reference book for decades to come. The listing is alphabetical and the work of each cartographer is analysed according to the number and size of maps produced, the limiting star magnitude, the co-ordinate system adopted, the date and place of publication, and the non-Ptolemaic constellations introduced. It is intriguing to note how certain constellations come and go. For example Lalande charted Felis, his own cat, and also introduced his telescope as Quadrans Muralis. Thomas Young squeezed the Battery of Volta into the space between the head and hooves of Pegasus. Julius Schiller even attempted to de-paganize the complete zodiac by introducing the twelve apostles in the place of Pisces, Aries, Taurus, Gemini and so on. The Warner catalogue is profusely illustrated in black and white and the beauty of these illustrations is most impressive. Obviously only a few of the maps were coloured and even this would probably have been a laborious task of hand water-colouring. It is hard to fault this book but may I make a suggestion for a new venture. If Deborah Warner produced a large-format book, with some colour prints depicting the best artistic

representations of each constellation, I'd be first in the queue with my money.

The transition between star maps, the beautiful, and star maps, the functional tool of modern science, is illustrated perfectly by the second book under review. Papadopoulos has produced a large set of maps by photographing the sky through a four-element astrographic objective lens manufactured by Carl Zeiss (Oberkochen). This lens had a diameter of 12.5 cm, a focal length of 62.5 cm and gave a negative with a usable field of 15°. Each map has been produced from the original negative by line reproduction, a system which prints only black, and has no halftones. This is ideal for stars but gives a very poor reproduction of the appearance of galaxies and nebulae.

The *Southern Stars* volume contains 120 maps covering the sky region from declination -30° to the South Celestial Pole. Each map covers an area of 11° by 11° and there is a minimum overlap of at least 1° between neighbours. The *Equatorial Stars* volume contains 216 maps and covers the region between -30° and +30° in declination. A set of transparent co-ordinate overlays are provided, six for Vol. 1 and three for Vol. 2. The system is converted to 1950.0. Each map measures about 33 cm by 33 cm. Volume 3, *Northern Stars*, will be published later this year.

The atlas is designed to show all stars which are brighter than visual magnitude 13.5 and, to quote the author, "the final print produces star images with easily readable differences in their diameters according to their magnitude". The accuracy with which the magnitude can be assessed obviously depends on the accuracy with which the star image diameters have been produced on the map and on the accuracy of measuring these diameters (a star of third magnitude is about 1 mm across). Superficially each map appears like a white sheet speckled with tiny black dots, surrounded by a black border with right ascension and declination markings on them so that the transparent grid can be positioned. To find your way between maps you are given a rather inadequate, small-scale, chart index. You actually need at least a copy of Antonin Bečvář's *Atlas Coeli* and preferably a set of Smithsonian Astrophysical Observatory star charts as well. The main advantage of the Papadopoulos atlas is that it goes down to visual magnitudes 13.5 as opposed to the SAO which stops about ninth. The main disadvantage is the price, but assuming you need to go down to 13.5 mag (and I would be very surprised if the number of astronomers who do really need to do this is more than miniscule) £245 for a collection of 336 Papadopoulos maps — Vols. 1 and 2 — is what you have to pay here. I must confess that I won't, and neither will my university. □

David W. Hughes is Lecturer in Astronomy and Physics at University of Sheffield, UK.

Thriving young discipline

Martin Daly

Human Sociobiology: A Holistic Approach. By D.G. Freedman. Pp.192. (Free Press/Collier Macmillan: New York and London, 1979.) £8.50. *The Genesis Factor.* By R.A. Wallace. Pp.256. (William Morrow: New York, 1979.) \$9.95.

HUMAN sociobiology seems to be a thriving young discipline, if a spate of books and new journals over the past two years is to be taken as evidence. Perhaps much of this activity will eventually be seen to be the cloaking of old ideas in new jargon, but much of it is truly synthetic. Sociobiology is gaining adherents among social scientists because, rather than contesting their established theoretical approaches, it is for the most part metatheoretical to their usual levels of analysis. Theories of sex role socialization, for example, may accurately describe processes by which masculine and feminine behaviour develop, while offering no insight into the cross-cultural consistency of the outcomes. Or a potlatch may be explained as a status competition, while taking it as a given that status is a commodity for which men will find it reasonable to compete. Sociobiological theory attempts to deal with some of the questions that structural, descriptive theories of human action fail to address.

If a "new synthesis" can indeed be said to be emerging, it is not surprising that anthropology, the social science most informed by evolutionary thought, is leading the way. However, sociobiological schools of thought have also surfaced in economics, sociology and even political science. The laggards whose participation is most seriously missed are psychologists.

The grounds for thinking psychology a crucial missing element in a productive synthesis are as follows. Anthropologists and other scientists testing sociobiological hypotheses have been concerned to demonstrate measurable fitness consequences of extant variation in behaviour, and they have achieved some notable successes (see, for example, chapters in *Evolutionary Biology and Human Social Behavior: An Anthropological Perspective*, edited by N.A. Chagnon and W. Irons; Duxbury Press, 1979). However, a good deal of modern human behaviour is manifestly not fitness-maximizing. Must sociobiology therefore be mute about its origins? Not if appropriate models of the structure of human motives and cognitive processes can be developed. The psychological mechanisms proposed must be anchored simultaneously in sociobiological accounts of their phylogeny and adaptive significance and in predictions of their behavioural outputs, including predictive

statements about the kinds of circumstances in which such evolved mechanisms can be expected *not* to produce adaptive outcomes. This task offers experimental psychologists a gold mine of opportunity for research and for theory development.

Daniel Freedman's *Human Sociobiology: A Holistic Approach* constitutes an early psychological foray into this rich field, and while the effort is deeply flawed, it nevertheless unearths several nuggets. The book's greatest shortcoming resides in the fact that Freedman ventures out of his depth in population biology. This produces two extremely distracting muddles. One, which surfaces repeatedly, concerns the significance of populational levels of heterozygosity. Freedman imagines that inbreeding is selected against not because of any deleterious effects of homozygosity upon the offspring of consanguineous unions, but because it constitutes "bad evolutionary planning" by reducing populational reservoirs of heterozygosity. He proceeds from this basic misunderstanding to characterize human populations as more or less heterozygous according to their marriage practices, a train of speculation which in Chapter 7 leads to several odd conclusions which leave the author needlessly vulnerable to accusations of racism.

The second major muddle is conceptually related to the first. Freedman has borrowed his University of Chicago colleague Michael Wade's suspicion of

MESOZOIC MAMMALS

The First Two-Thirds of Mammalian History

Edited by Jason A. Lillegraven

Mammals have been an important part of the earth's land fauna for at least 200 million years. This book offers a comprehensive review of what is known about mammalian life during the first two-thirds of its history — the Mesozoic era — before the extinction of the great reptiles. The book provides biologists and geologists with encyclopedic listings of fossil locations, recognized taxa, and temporal-geographical occurrences of genera along with descriptions of the anatomical features of each group and extensive bibliographies. Interwoven with the summaries of data are valuable interpretive — sometimes admittedly speculative — discussions of the origins of mammals, their patterns of distribution, and their biological, behavioral, and evolutionary relationships during the "dark ages" of mammalian history. Illus. 320 pages £21.00, cloth £5.75 paper.

UNIVERSITY OF CALIFORNIA PRESS

Circle No. 52 on Reader Enquiry Card.

"selfish gene" reductionism without apparently grasping the rationale for that suspicion. The undisputed fact that social groups have complex interactive properties which may be mistaken by researchers focussing attention on individuals is thoroughly confused with the question of the roles of group versus individual selection in the evolution of adaptation. I am not cavilling on this subject, for the author's imagined critique of individual selection is a major, recurring theme of the book. He begins Chapter 4 with this paragraph (page 45):

I hope I have by now established that both the selfish-gene approach from below and the group selection approach from above are needed for an adequate explanation of social behavior, no matter the species. When we get to primates, the need for a dual causality model rather than a one-way model is emphasized since primates can act with clear selfishness or in concert, as the situation demands.

By this point, sociobiologically sophisticated readers may have decided to take a walk, and that is a pity, for the book's strengths lie just ahead.

One strong feature is Freedman's cross-cultural review of sex differences in the behaviour of human children. Cultural anthropologists have seldom standardized methodology or collected quantitative data, so the psychologist's touch is valuable here. Among the many interesting phenomena described are the prevalence of acknowledged hierarchies of "toughness" among small boys and the irrelevance of the same dimension for girls. Also intriguing are data on children's drawings, in which thematic sex differences are highly consistent across cultures even as substantial between-cultures variation is manifest.

Fifty student research projects carried out under Freedman's aegis (and outlined in a fifty-page appendix) are discussed in the text. Though highly variable in quality, these studies introduce a number of innovative methods and provocative findings. For example, modified TAT cards (pictures about which subjects are invited to tell a story) are used to assess the emotional impact and status significance of facial hair and of relative height, with results that sometimes contradict the respondents' professed attitudes. In a similar vein, the dimension of kinship is added to another standardized psychological instrument, Kohlberg's Moral Dilemmas, in order to provide evidence that people apply different moral codes to kin and non-kin. The use of such techniques should inspire readers interested in developing a socio-biological psychology.

The concluding chapter, entitled "Biology or culture?" begins with a not altogether successful attempt to dismiss such unproductive either-or-ism: "There is no way to separate the genetic and the learned for they are permanently glued together, and that is true everywhere in nature, including man". Heaven knows what is meant by "learning" if it is

manifest "everywhere in nature", but most readers will probably find the sentiment acceptable if not the logic offered in support of it. Freedman then reviews his own convincing evidence for population differences in human infantile behaviour and temperament, proceeds to speculate plausibly that such differences may be causal to non-arbitrary cultural differences, and somehow concludes that racial "antagonisms are more or less built into the species" and that "the only sound solution lies in miscegenation". One is left perplexedly leaving back, vainly trying to reconstruct the extraordinary logic of this argument.

Robert Wallace's *The Genesis Factor* is blurred as "the first popularly written book on sociobiology". If popular writing consists in talking down to one's readers and in disdaining to cite sources, the characterization is correct. Popular writing also apparently entails a suspension of respect for fact. Here are just three examples: parental care occurs in "only a few isolated species" of fishes (page 37); gorillas are "highly promiscuous" (page 76); and the administration of androgens to infant female mice transforms them into killers

without interfering with normal oestrus (page 116). Even where a particular experiment is under discussion, Wallace is liable to serious mis-statement of the results, as in his treatment of Harry Power's mountain bluebird removal experiments (page 179). Running roughshod over such disparate subjects as IQ and the alleged adaptive value of death, Wallace's book will regrettably reinforce antibiological prejudices of some social scientists while proving an embarrassment to thoughtful biologists. It ends on an even more remarkable note than Freedman's book, namely the author's personal foreign policy recommendations for the United States government! With friends like Wallace, sociobiology has no need of enemies.

Let us hope that we will see more and better empirical work of the sort initiated by Freedman. And may we have fewer grand statements of the policy implications of human sociobiology, at least until the discipline grows up a little. □

Orcadian heritage

Euan W. MacKie

Investigations in Orkney. By Colin Renfrew. Pp.234. (Society of Antiquaries: London. Distributed by Thames and Hudson: London, 1979.) £20.

UNTIL the recent oil discoveries the Orkney Islands seemed remote from and peripheral to modern Britain, yet several times in the past they have been at the crossroads of important movements of people and influences. These usually came either up the western seaways from Atlantic Europe, like the stone tomb-builders of Neolithic times and elements among the inventors of the Iron Age tower-forts known as brochs, or, like the Norsemen and the Early Bronze Age Beaker people respectively, westwards from Scandinavia or north-westwards from the Low Countries or the eastern mainland of Britain. Like the churning cross-currents of the Pentland Firth, these genetic and cultural mixtures often produced periods of striking local developments in the islands. The sandstone of which these are formed provided ideal building material and some remarkable developments in drystone architecture resulted.

Archaeological research in Orkney has been sporadic in the past with long periods of inactivity, but the early 1970s saw a burst of new work by visiting excavators. Sites

like the Neolithic dwellings at Skara Brae and Knap of Howar, the Pictish and Norse village at Buckquoy, the prehistoric and early historic settlement at Skaill and the Neolithic chambered tomb at Quanterness (the main subject of the book) were explored with modern techniques for the first time. Knowledge is still advancing rapidly through the efforts of a new resident team of archaeologists financed by the Scottish Development Department, the North of Scotland Archaeological Services Unit based at Finstown.

Professor Renfrew has long been concerned to explain in modern terms the dramatic changes visible in the prehistoric archaeological record, such as the appearance of the chambered burial mounds of Atlantic Europe at around 4200 BC, and he favours hypotheses of indigenous development rather than any involving the diffusion in some way of ideas and skills from more advanced cultures. The radiocarbon dates for the earliest European chambered mounds have in any case shown them to be older than those of the Early Bronze Age in the Mediterranean world which were originally suggested as prototypes. Another aspect of this new approach is the interpretation of the tombs in terms of the kind of societies which built them and of the environment in which these people existed. The cairn at Quanterness is the first in Orkney to have been investigated with these general problems in mind.

One example of the detailed mass of evidence collected may be cited.

REIDEL'S SPRING LIST

Bifurcation Phenomena in Mathematical Physics and Related Topics

C. BARDOS, D. BESSIS (eds.)

Covers many aspects of phenomena arising from non linearities in mathematical physics and applied mathematics with emphasis on mathematical theory of bifurcation and on bifurcation in statistical physics.

about 602 pp. Cloth Dfl. 115,-/US \$ 59.50
ISBN 90-277-1086-4

Astrophysics from Spacelab

P. L. BERNACCA, R. RUFFINI (eds.)

Highlights the new facilities made available by the combination of the shuttle and spacelab programmes with special emphasis given to the implications of these programmes for fundamental physics and astrophysics.

about 720 pp. Cloth Dfl. 90,-/US \$ 47.50
ISBN 90-277-1064-3

Bioenergetics and Thermodynamics: Model Systems

A. BRAIBANTI (ed.)

Employs the thermodynamic data on synthesised organic compounds with special reference to macrocyclic ligands for the interpretation and prediction of energetic processes involving small and large molecules.

493 pp. Cloth Dfl. 110,- / US \$ 58.00
ISBN 90-277-1115-1

Semiclassical Methods in Molecular Scattering and Spectroscopy

M. S. CHILD (ed.)

Discusses and analyzes all developments in the scattering field during the last 20 years including the JWKB approach, tunneling and curve-crossing situations, and non-separable situations.

about 342 pp. Cloth Dfl. 75,-/US \$ 39.50
ISBN 90-277-1082-1

Horizons of Quantum Chemistry

K. FUKUI, B. PULLMAN (eds.)

Contains the proceedings of the 3rd International Congress of Quantum Chemistry held in Kyoto 1979. Constitutes a broad and up-to-date encyclopedia of our knowledge of quantum chemistry and is important to teachers and researchers in this subject.

about 296 pp. Cloth Dfl. 75,-/US \$ 39.50
ISBN 90-277-1105-4

Heavy Gas and Risk Assessment

S. HARTWIG (ed.)

Discusses risk analysis and behaviour of

LNG, LPG, chlorine, etc., as well as analysing flammable vapour clouds. Of prime importance to the chemical industry, government and local authorities, safety and transport experts.

about 355 pp. Cloth Dfl. 70,-/US \$ 37.00
ISBN 90-277-1108-9

Atmospheric Physics

J. V. IRIBARNE, H.-R. CHO

Elementary and comprehensive textbook on the terrestrial atmosphere for 2nd and 3rd year university courses. Requires only basic knowledge of physics and mathematics and contains a list of questions and problems designed to give a better insight into the various subjects discussed.

about 215 pp. Cloth Dfl. 40,-/US \$ 15.95
ISBN 90-277-1033-3

Experiment, Theory, Practice

P. L. KAPITZA

Contains articles and addresses by this Russian Nobel Prize physicist including material on his scientific work, the founding of the Institute for Physical Problems in Moscow, the links between science and industry, his ideas on educating the youth, recollections of Lord Rutherford and his other contemporaries, and his public interests like ecology and disarmament.

449 pp. Cloth Dfl. 90,- / US \$ 47.35

ISBN 90-277-1061-9

SERENGETI

Dynamics of an Ecosystem

The Serengeti National Park in Tanzania contains some of the largest herds of grazing mammals found anywhere in the world, making it an incomparable resource for the scientists who have contributed to *Serengeti: Dynamics of an Ecosystem*. Starting in the 1950s and expanding in the 1960s with the formation of the Serengeti Research Institute, the group examined numerous biological aspects of the ecosystem in order to make recommendations for the area's conservation. This book synthesizes some aspects of the processes and patterns studied in this tropical savanna over the past twenty years; the emphasis is on the changes that have taken place and the development of ideas on how the system functions. March 1980, 384 pages, 32 plates, £17 10.

The Knowe of Yarso, Rousay.

Quanterness is an architecturally sophisticated tomb and its period of use was determined by radiocarbon measurements to between about 3200 and 2500 BC. (This itself is important as it shows clearly that the tomb is relatively late in the Neolithic period and in the Orkney series, refuting again the old diffusionist theories which demanded that the most

sophisticated buildings were built first, by the original skilled colonists.) The number of individuals buried collectively — generation after generation over a period of 550 ± 180 years — in this great roofed stone vault was estimated from the thousands of disarticulated human bones recovered to be about 400. Both sexes and most age groups were represented, and the

conclusion drawn is that all the members of a small farming community of 13–20 people were buried in the cairn.

These results, and those of the many other detailed researches carried out, form a landmark in our understanding of Orcadian Neolithic society — a mass of hard evidence which will provide a minimum standard for all future work. My only doubts concern some of the conclusions drawn from the data, particularly the failure to consider in any way — even simply to dismiss it — the alternative social interpretation of these cairns. This, argued in some detail in my book *The Megalith Builders* (reviewed in *Nature* 270, 644; 1977), suggests that the people buried in the cairns could have been the members of a non-farming section of the Neolithic population, most probably of religious orders which were linked genetically and by shared architectural and funerary traditions to the other cairn builders all over Atlantic Europe. The work at Quanterness has not disproved this interpretation unless this is considered to have been achieved by the author firmly looking the other way. □

Immortalized in a virus

D.H. Watson

The Epstein-Barr Virus. Edited by M.A. Epstein and B.G. Achong. Pp.459. (Springer: Berlin, Heidelberg and New York, 1979.) £34.50.

EPSTEIN-BARR (EB) virus was discovered in 1964 by the two workers immortalized in its name; they identified particles with the characteristic morphology of the herpesvirus family in lymphoblasts cultured from a lymphoma of a type first described in African children by Burkitt in 1958. The first chapter in this volume is an account by Epstein and Achong of this early work in which Epstein's inspiration was to examine cells cultured from the tumour after an earlier fruitless search in biopsy cells.

Since 1964 a formidable body of published work has been amassed by workers from a wide variety of disciplines using an impressive array of biochemical and biological techniques. The remaining articles in this volume, written by a number of those who have made notable contributions, summarize and review progress since 1964.

Serological studies played an important initial role, and an early chapter by Ernberg

and Klein is appropriately devoted to an account of EB antigens. This sets the stage for a description by the Henles of their notable serological studies, which not only identified EB virus as distinct from other herpesviruses but most unexpectedly showed that the virus was ubiquitous, often occurring in leukocytes of healthy donors in many parts of the world. This led to the link between the virus and infectious mononucleosis and also with a second rare malignancy, nasopharyngeal carcinoma. Plainly the major stumbling block was the lack of a unique or even consistent relationship of the virus to the malignant conditions.

Molecular hybridization studies, excellently described in articles by Pagano and Shaw and by zur Hausen showed, however, that virtually all nasopharyngeal carcinomas and African (if not American) Burkitt lymphomas contained virus DNA.

There still remained the difficulty of explaining why such a widely distributed virus apparently produced tumours in restricted geographical areas. Burkitt himself suggested that a malarial co-factor might account for the lymphoma but although, as indicated in a later chapter by Epstein, there is supporting evidence for this idea, it would seem that it cannot be a unique co-factor given the comparative rarity of the lymphoma, even in its favoured locale, in doubly infected individuals. Others have argued for strain

variations in the virus and this is discussed in the chapter by Pagano and Shaw as well as by Miller.

A further twist to the tale is provided by the recognition that the virus DNA may sometimes exist in the cell in a non-integrated ('episomal') form and at other times be integrated as described here by Adams. He, like Pagano and Shaw, envisages the rare change to malignant transformation from non-malignant proliferation as being mediated by insertion and operation of transforming sequences.

The other chapters are equally absorbing, dealing with aspects as varied as the recent IARC prospective sero-epidemiological survey (de Thé; see also *Nature* 274, 756; 1978), prospects for vaccine control (Epstein), and comparative studies on oncogenic herpesviruses (Deinhardt) — to make what must in the space available be an arbitrary selection.

The volume will be useful to those from many disciplines in which EB virus has become important, in providing them with a useful statement of the current situation. Even those directly involved in the large numbers of publications on the virus will welcome the presentation in one place of such a wide-ranging survey. □

They touched the nerve of the Universe

V.F. Weisskopf

The Early Years: The Niels Bohr Institute 1921-1930. By Peter Robertson. (Akademisk Forlag, Denmark, 1979.) £6.

THIS book is a short account of the first ten years of Niels Bohr's famous Institute for Theoretical Physics. This institute was the scene of one of the most revolutionary and far-reaching developments in natural science, the birth of quantum mechanics. In some ways it was also the first international scientific institution, not in the sense of being internationally managed, but by having assembled, for shorter or longer periods, groups of young and productive physicists from many countries. Their names include most of the great leaders in physics such as F. Bloch, H. Casimir, P.A.M. Dirac, P. Ehrenfest, G. Gamow, W. Heisenberg, L. Landau, W. Pauli and many others. It was at that time, and with those people, that the foundations of the quantum concepts were created. In lively discussions the deepest problems of the structure of matter were

At the Institute early in 1931, Lev Landau, George Gamow and Edward Teller with two of Bohr's sons, Aage and Ernest.

conventional bonds, and a spirit of joy that can hardly be described by anyone who was not there at that time. In this great period of physics Bohr and his collaborators touched the nerve of the Universe. They were able to penetrate into the inner workings of nature that had been a secret up to this point. In the course of a few years only, the basis was laid for a science of atomic phenomena that grew into the vast body of knowledge known to us today.

The book by Robertson tries to recount the events that led to the foundation of that institution and the happenings during its first decisive and creative decade. It is the result of a painstaking research into the history of this unique institution. The author gives a lively and easily readable account in a little more than 150 pages, but one notices that he was not there at the time. We read about the early attempts to create a centre of international physics after the ravages of the First World War had interrupted scientific collaboration;

we read about the bureaucratic and financial difficulties that were overcome only with support by the Rockefeller Foundation; we read about the different scientists who came to the institute and about their work and their conversations with Bohr. One of the most attractive features are the many photographs of the institute, of the physicists, singly and in discussions, and of conferences and meetings that had taken place in Copenhagen and elsewhere during that period.

Reading this book and looking at the pictures is a nostalgic experience for those who had the privilege of being in contact with Bohr's institute in one way or another. I am not sure how much of the spirit and of the intellectual achievements of the institute is transmitted to a reader who has not had that great privilege. □

V.F. Weisskopf is Institute Professor at Massachusetts Institute of Technology, Cambridge, Massachusetts.

George Gamow and Wolfgang Pauli on a lake steamer in Switzerland.

brought to light. N. Bohr was the acknowledged leader; he created a style of thinking, the "Kopenhageuer Geist". The greatest among his colleagues, he was acting, talking and living as an equal among a group of young, optimistic, jocular, enthusiastic people, approaching the deepest riddles of nature with a spirit of attack, a spirit of freedom from

Ape language, cognition and culture

Carolyn A. Ristau

The Ape's Reflexion. By Adrian Desmond. Pp. 288. (Blond and Briggs: London; Dial Press/James Wade (Dell): New York, 1979.) £7.95, \$10.95.

THE APE'S REFLEXION is man; the possibility of the ape reflecting has created recent controversy. Is the ape capable of some primitive language; how extensive are his cognitive abilities; does the ape murder; does he have a sense of self and of death? Adrian Desmond deals with these momentous concerns in what I presume is intended to be a semi-popular book. His writing style is often fluid and he frequently achieves a sense of immediacy, seeming to

give an eye-witness account of the research. One can easily nestle down with his book for a few evenings' light reading. The sense of an eye-witness account is apparently not based on any visits by the author to research in progress. This is unfortunate, for an objective, careful and critical reporting of anecdotal information would be a useful addition to the literature on the ape language projects. The scientific literature suffers from a lack of such information while the popular literature abounds with dramatic and careless reports.

Briefly, Desmond's book concerns itself primarily with the ape language research projects, the neuroanatomical comparison of man and chimpanzee, tool use and proto-cultural activities of chimpanzee and early man, and some of Jane Goodall's investigations at the Gombe River Stream Preserve. There are numerous direct quotations from researchers' studies, an index and footnotes. The footnotes,

located at the back of the book, indicate references and sometimes offer detailed discussions. An alphabetical list of references and more such discussion would have been useful additions. The book also contains 24 pages of black and white photographs, predominantly of chimpanzees from the language projects and the Gombe River Stream.

Desmond considers man's close genetic relationship to the chimpanzee, citing 99% similarity in DNA nucleotides. Yet he does not note that the 1% difference appears to control timing and sequence of genetic expression, a mechanism by which organisms can develop very differently from each other. Furthermore, overall genetic similarity or dissimilarity need bear no necessary relation to the similarity of particular attributes of any two species. A dolphin is physically very different from man, yet may have certain cognitive abilities that are similar to man's. Desmond's comparisons between the Gombe River chimpanzee killing and man's act of murder, as well as many anecdotes from the ape language projects, are other examples of dramatic interpretations of data that need further analysis.

Desmond does raise important points. For example, in Desmond's consideration of the ape language work, Wittgenstein's aphorism, "If a lion could speak we could not understand him" (p.33), is quoted in reference to the naive assumption often made by trainers that chimpanzees use signs like 'please' and 'think' with the meanings assigned to them by humans (p.35).

Desmond also describes the recent investigation of Savage-Rumbaugh *et al.* (p.107) into the meaning of an utterance. Their chimpanzees seem to have the ability to use a lexigram or geometric design such as the design for 'key', in a highly specific context, but become bewildered upon its application to a wider array of contexts.

That is, the chimpanzees seem to recognize that use of the lexigram for key will initiate a chain of events that eventually leads to their obtaining food with a key, but do not seem to understand that the lexigram is the 'name of' a key. Gradually some kind of understanding closer to that level does seem to be achieved, but the research makes it clear that a chimpanzee's (or young child's?) appropriate use of a 'word' in a limited number of contexts does not imply understanding of the word.

However, as Desmond notes, words *can* 'map on' to thought. Premack conceptualizes his 'ape language' investigation as permitting apes to use words to map out conceptual structures the animal already possesses. The end of the work is thus not to teach an ape language or to wonder how linguistic the apes' abilities are or are not, but to use the ape 'language' as a tool for revealing some of the apes' cognitive capacities.

Throughout, Desmond wisely emphasizes that we cannot measure apes with a human yardstick.

Another of the more positive parts of Desmond's book is his exciting account of the trail of discoveries initiated by analysing soil samples and leading, finally, to the discovery, in the molecules of soil, of flowers at the grave of a Neanderthal man. Here was an indication of some ceremony for the dead, a remnant of culture in so early a hominid.

In all, Desmond does consider fascinating issues and offers some insightful thoughts. But one wishes at least for less wordiness, more dispassionate writing and less uncertainty about the validity of his interpretations. And does the reader need to find phrases like "Oh Darwin, where art thou now?" □

Coulson's Valence

Linus Pauling

Coulson's Valence. Third edition. By R. McWeeny. Pp.434. (Oxford University Press: Oxford, 1979.) Hardback £17.50; paperback £8.50.

A SIMPLE but very powerful theory of chemical valence and the structure of molecules, especially of compounds of carbon, was developed in the period between 1852 and 1874 by E. Frankland, F. A. Kekulé, A. S. Couper, A. M. Couper, A. M. Butlerov, J. H. van't Hoff and J. A. Le Bel. It was extended in 1893 by A. Werner to include complexes of metals, which he identified correctly from chemical evidence as representing tetrahedral, square planar or octahedral coordination of ligands about a central metal atom. An important contribution to

the theory was made in 1916 by Gilbert Newton Lewis, who described the chemical bond as a pair of electrons held jointly by two atoms and who emphasized the stability of molecular structures in which each atom is surrounded by the same number of electrons as in a neutral noble-gas atom. Important contributions, such as the principle of electroneutrality and possible covalence as large as eight (for nickel in nickel tetracarbonyl), were made by Irving Langmuir from 1919 to 1921.

Despite some clarification introduced by the new ideas about the electronic structure of atoms and molecules, the theory of valence and the structure of molecules and crystals clearly remained incomplete. Many questions were asked in the first half of the 1920s that could not be answered; for example, why are the aromatic hydrocarbons more resistant to hydrogenation than other unsaturated hydrocarbons, why do complexes of palladium(II) and

New Books in the Life Sciences

Dental Plaque and Surface Interactions in the Oral Cavity

Edited by S. A. Leach

Proceedings of a workshop held November 1979 at ICI Pharmaceuticals Division, Macclesfield, U.K.

Comprises 20 papers presented under the following session headings:

Surface and colloid phenomena in relevance to the mouth; Bacterial adhesion to tooth surfaces; Some factors that might affect plaque formation; The tooth-saliva interface.

340 pages. Illustrated.

platinum(II) have the square planar structure whereas those of zinc(II) and cadmium(II) are tetrahedral, why are most compounds formed from the elements with a decrease in enthalpy, and most basic of all, why does sharing a pair of electrons between two atoms lead to a bond that holds the atoms together? The answers to these and many other questions were found in the period 1927 to 1933 through the application of the newly discovered theory of quantum mechanics to the problems. In 1927 ϕ . Burrau published his quantum-mechanical treatment of the one-electron bond in the H_2^+ molecule-ion describing the first molecular orbital, and in the same year E. U. Condon treated the electron-pair bond in H_2 by the molecular-orbital method, and W. Heitler and F. London treated the same problem by the prototype of the valence-bond method. In 1926, and in greater detail in 1931, I introduced the concept of hybridization of bond orbitals, and between 1931 and 1933 I discussed the quantum-mechanical basis of tetrahedral, square planar and octahedral coordination, ionic-covalent resonance energy, the electronegativity scale, magnetic properties of complexes, the structure and properties of aromatic and conjugated molecules, and several other matters relating to valence and molecular structure.

Between 1928 and 1931 the quantum-mechanical theory of the resonance of a

system between two or more possible structures and the consequent stabilization of the system by resonance energy had been discussed by John Slater, by me and by E. Hückel, and Slater had, in 1931, formulated his expression for the wave function representing an assigned valence-bond structure for a molecule. Many detailed quantum-mechanical calculations were being made of molecular properties by both the molecular-orbital method and the valence-bond method, and in 1931 both Salter and I published closely similar short papers to point out that, whereas these two methods in their simplest forms gave somewhat different results, when refined they approached each other, ultimately becoming identical.

During the 50 years since these events took place molecular quantum mechanics has made great strides. Many extensive calculations have been carried out, mostly with emphasis on molecular orbitals. I chose, however, to attempt to refine the theory of the chemical bond in a semi-empirical way, incorporating the ideas and principles of quantum mechanics. The results of this effort, in which I adhered as closely as possible to the ideas of classical valence-bond theory, were described in 1939 in my book *The Nature of the Chemical Bond* (third edition Cornell University Press: Ithaca, New York, 1960).

In the first edition of his book *Valence* (Oxford University Press: Oxford, 1952),

Professor Charles Coulson emphasized the molecular-orbital description of electrons in molecules, with rather little discussion of empirical information. This policy has been followed by Professor McWeeny in preparing the much enlarged third edition. The result is that the book contains only a small amount of information about valence. There is no significant discussion of oxidation number, the range of values of the valence shown by many elements, and a number of other aspects of valence theory. Instead, as the author states in his preface, the book provides an introduction to quantum mechanics and a discussion of the application of quantum mechanics to the structure of molecules, with emphasis on the molecular-orbital method (which the author describes as having largely superseded the valence-bond method). The level of the discussion is for the most part rather high, but there are some surprising exceptions, such as the failure to derive the wave functions for the hydrogen atom. The book provides a survey of molecular quantum mechanics and of some aspects of structural chemistry. An isolated student without previous knowledge of quantum mechanics might find it difficult, but it could serve well as the textbook in a course, the purpose for which it was written. □

Soviet innovation

Christopher Freeman

Science and Industrialisation in the USSR: Industrial Research and Development, 1917-1940. By Robert Lewis. Pp.211. (Macmillan: London, UK, 1979.) £12.

OVER the past 20 years the Birmingham Centre for Russian and East European Studies has established a high reputation for carefully documented research on Soviet R&D and industrial innovation. This book will certainly enhance that reputation and in many ways is even more interesting than its predecessors. Although it is entirely concerned with the inter-War years, the great interest of this period is that it was the formative time when the structure and procedures of the Soviet industrial innovation system became firmly established. It is also remarkable how many of the post-War debates in Western Europe were anticipated in the pre-War controversies in the USSR. Who remembered, for example, that the Rothschild "customer-contractor" principle was enthusiastically introduced in the Soviet institutes 50 years before its application here?

The new Soviet state inherited a science-technology system in 1917 which had many of the characteristics of today's under-developed countries — dependence on foreign technology and an almost complete lack of industry-based R&D. The Soviet leaders attempted from the outset to build up their own industrial R&D system, and the expansion in the 1920s and early 1930s was much more rapid than elsewhere. Indeed the Soviet Union has probably spent a higher proportion of its national income on scientific and technical activities than any other country for about half a century now. In absolute terms, this was, of course, still a fairly small total in the 1930s and as Robert Lewis is careful to point out "R&D" is only one part of the total rubric "science and technology". Definitions of R&D differ between Eastern and Western Europe and in any case were only formulated after the Second World War.

The first few chapters of the book document the growth of the Soviet science-technology system during the inter-War years with scrupulous attention to detail. (In a 200-page book, 50 pages are devoted to sources and methods.) The next few chapters review the organization of the system and the various attempts to control, coordinate and plan it. Finally, the last three chapters analyse this experience

critically with a particularly interesting discussion in Chapter 10 on "Yesterday and Today". They seek to answer the question: why has the return on the massive Soviet R&D investment been so unsatisfactory?

Robert Lewis concludes that the major structural weakness of the Soviet industrial R&D system was the failure to build up a strong R&D capability at the enterprise level and that this weakness persists to this day despite a succession of attempts to overcome it. Shortages of skilled manpower and equipment as well as the desire to avoid expensive duplication dictated the early decisions to concentrate the industry-related R&D in central institutes for each branch of industry. Ever since then, there has been a continuous theme of complaint that the central institutes were too remote from the real problems of the factories and conversely that industry had neither the capacity nor the incentive to apply the results of the R&D conducted in the central institutes.

This problem is by no means confined to the Soviet Union or to centrally planned economies. Even within large private enterprise, it is a familiar theme of the R&D management literature. In one form or another it is likely to persist even in the best-managed systems as it reflects a real difference in preoccupation and pers-

pective between those primarily concerned with the management and improvement of an existing production system and those concerned with potential changes in products and processes including the total displacement of existing systems. However, there seems little doubt that the problem was particularly acute in the Soviet Union as institutional barriers were reinforced by geographical and political constraints. Lewis shows that, despite many declarations of good intentions about decentralization, the R&D establishment remained overwhelmingly concentrated in the Moscow and Leningrad regions. He calculates that a decade of pressure resulted only in a reduction of the proportion employed in these two regions from 80% to 75%. Again, this is by no means exclusively a Soviet problem.

The final chapters suggest, although not very explicitly, that the most important specific Soviet weakness has been the over-centralization of decision-making associated with Stalinism. It is of some interest that already in the 1920s Pyatakov and other members of the "Left" opposition were advocating the wholesale decentralization of industrial R&D to the enterprise level. The combination of the output target system, the import of 'turn-key' foreign technology, the shortages of skilled people and the decimation of the intelligentsia in the purges of the 1930s meant that the various attempts which were made to strengthen enterprise-level R&D had little effect.

The major exception which Lewis points to was the aircraft industry, and the discussion of its peculiarities in Chapter 9 is one of the most interesting in the whole book. This industry was a high priority for the leadership throughout the 1920s and 1930s which found expression both in a relatively lavish level of funding and in a readiness to change the organizational system in order to get the results so urgently demanded by Stalin and other leaders, who apparently showed an almost daily interest. Whereas in other industries it was difficult to get adequate resources for prototype and pilot plant work, in the aircraft industry several alternative designs were often promoted simultaneously right through to the prototype test stage in development. In the aircraft industry too, the single central research and design institute gave birth to a pluralistic structure already in the early 1930s which included the rather successful flexible design groups assembled under the leadership of individual designers and sometimes located at factories.

Centralization to a high degree certainly persisted in the aircraft industry, but it was combined with a real choice in design and development based on autonomous effort and with relatively good communications with the production systems. An interesting point made by Lewis is that sometimes factory personnel were brought into the design and development teams at a fairly

early stage. He does not discuss it, but one may guess that this industry also made good use of its own products to ease the physical communication problems of the USSR.

By preventing Germany and Japan from embarking on expensive aircraft, nuclear and other military R&D projects for two decades after the Second World War, the USSR and its War-time allies conferred upon them the inestimable blessing of concentrating most of their best engineering and scientific talent on the industries which really mattered for economic growth and international trade performance. The results are now increasingly apparent. The British in a mild way since 1945 have suffered from the Russian problems of the 1930s — too high a priority for R&D in prestige defence-related industries and relative neglect of the

rest. As in the USSR, a very high proportion of our best science and engineering talent was locked into this system for 30 years, while the mechanical engineering industries, vehicles and other mundane branches of the economy did not have the capacity to design and develop new products to keep pace with world competition. To this day, they do not have and often cannot get the electronic engineers they need to re-design their products and processes. It would be ironical if the 'Iron Lady' in her anxiety to combat the Soviet 'menace' caught a more virulent strain of the Russian 'flu'. □

Voyages through the cosmic landscape

D.D. Clayton

Cosmic Landscape: Voyages Back Along the Photon's Track. By Michael Rowan-Robinson. Pp.149. (Oxford University Press: Oxford and New York, 1980.) £4.50.

WHEN I began this book I was somewhat prejudiced against it because I thought it would sink from the burden of its seemingly unnatural standpoint. After all, astronomical knowledge has exploded from the combined measurements of astronomical objects by instruments responsive to the different spectral bands. Yet, here Michael Rowan-Robinson presents "cosmic voyages in each of the main wavelength bands of contemporary astronomy". He finds himself "taking this metaphor of voyage literally, and describing how I think things would look from a viewpoint different to that seen from earth. Certain objects in the cosmic landscape figure in several different wavelength bands and so our picture of them builds up only gradually from the succession of voyages in each band". Surely, I thought, the only way to discuss the Crab Nebula, or QSO 3C 273, would be from the simultaneous knowledge from all types of measurements, and not from a succession of half-blind glimpses. But in the end my negative predisposition was overcome by an informative and often poetic presentation. This is a very good book, although it fails by slim margins to be a great one.

The author says, "I have tried to write a book for someone who might never have read anything about astronomy". So restricted, he must at times be a teacher: "What is light?"; "What is colour?"; "How is light made?"; "What are radio waves?" are subsections of chapters in which he must also explain such phenomena as atomic and molecular structure and radioactivity without seeming to delay forever the departure of the cosmic expresses. Amazingly, he has surmounted this obstacle with as much grace as one can hope for. He does this by appealing to general matters of human interest — for example, by describing briefly the red, green and blue-light-sensitive organic pigments in the cone-shaped detector on the back of the human retina. Occasionally, he forgets this audience and uses technical terminology that can only impede the novice; for example, because he uses it he must explain that in writing O VI "the Roman numeral corresponds to one more than the number of missing electrons". The book is, I think, a bit difficult for readers without scientific backgrounds; but the author has made a good compromise between simplicity and the inspiration of real intellectual content. For this reason, I will recommend this book to nonprofessionals interested in astronomy, even knowing they will not understand some of it.

So we set off in succession on six voyages: the visible landscape; the radio landscape; the ultraviolet landscape; the X- and γ -ray landscape; the infrared landscape; and the microwave landscape. I could not discern the author's reason for this order; but neither can I criticize it as illogical or inappropriate. Perhaps putting the infrared landscape off until the fifth voyage has something to do with the author's personal research emphasis. It warms him especially to this voyage, causing him to note here, almost sadly, that totally new surveys of the sky seem to be

now a part of history, and then to the confession: "For me it has been a wonderful time to be alive and to be an astronomer. And so I try to share this experience with you".

To analyse the success of this book I must, like the author, branch out from astronomy into the larger realm of human experience. A landscape is interpreted as a partly subjective human experience, with the human at its centre. Its objective, in an artistic sense, is not the description of the separate parts of the scenery, but rather a description of the act of perceiving it. Rowan-Robinson has not idly chosen a catchy title; he has chosen it specifically to his artistic purpose. The ponderous structure of separate voyages in different wavelength bands succeeds because his purpose is not to explain our understanding of the objects in the landscapes, but rather the human act of perceiving them. He evokes, perhaps unintentionally, the experience of the child in its crib, looking out at baubles hanging above him and wondering at the meaning of a perception he cannot touch. It is a powerful undercurrent that gives

force, by its repetition, to these cosmic voyages. The reader glimpses the human race in its infancy, reaching out.

I cannot say that Rowan-Robinson intended all of this, but I believe that he did. As someone who has also attempted to enlarge the genre of scientific writing, I can only admire his effort. It falls short of greatness because the author was not sufficiently single-minded in this task. The pedagogical explanations weigh down the poetic experience. We have here the artist painting his landscape and, at the same time, explaining to us how we know that the water in the creek flows downhill rather than up. On the positive side of that coin, however, there is fascinating astronomical and physical knowledge interestingly described on each page. So it is also a book from which to learn about astronomy. For a skilful blend of these objectives, the author earns grade A. I remain fascinated with the partially fulfilled opportunities of this book as a poetic and artistic experience. I can best share this fascination by the following poem, which this book inspired me to write:

On His Reading *Cosmic Landscape*

Hanging there on strings, tiny baubles above my crib,
What would I name you if I, like they, knew words?
Jupiter, Venus, pulsar, quasi-stellar objects of my gaze,
Abstaining from warm flesh from which I grew,
You surely breathe and eat and cry like I.
For what can I now know of death, of that passage
That will one day threaten the incomprehensible world?
Silently they hang above me, beyond my reach, unreal . . .
Unreal at least except for eyes, mystical extensions,
Touch without fingers, motion without impact, something there,
But maybe not important, milkless, without warmth.
Still, you must have a name, a kind of category,
Something that can let me live at peace with you.
Could I but sense you in my way, some measure perhaps,
Could I but bridge the gulf that lies between,
Maybe I would do so, but how? what do I need?
A name is fine, but will it shore up liberty
From ignorance, from lack of touch, from measurement?
From measurement! What new idea now swarms within me?
Perhaps a mathematics, calculations from untouchables
Can clarify your orbit, predicting perigee perhaps or self collapse.
Unending accusations drain this dream: worthless metaphysics,
Not a method to trust, yet my heart does beat to it.
Have ancient genes bestowed on me this thrill,
Forgotten values to mankind accrued to permanence in me?
Urging explorations, voyages from this nursery,
They inflame my nerves where comfort never can.
Rattlesnakes see infrared and suffer no abject demise,
Bats somehow hear a soundless noise, compressibilities,
But all the same to me, here, not knowing, ignorant,
Wondering simply what it means to see beyond,
And if this oh-so-childish room will stand the test
Of time, when I no longer am its nexus.

An optimist's selection of nightmares

Peter J. Smith

A Choice of Catastrophes. By I. Asimov. Pp. 377. (Simon and Schuster: New York, 1979.) \$11.95.

IMAGINE a small black hole about the size of the average asteroid and with a mass of, say, a millionth of that of the Earth. Suppose then that this remarkable object were to enter the Solar System and score a direct hit on the Earth. What would the result be? The "mini-black hole" would tunnel its way into the planet, absorbing matter and thus growing as it went. If it had sufficient momentum to begin with, it would burn a path right through the Earth, causing enormous explosions where it entered and left. At the points of entry and departure life would stand little chance of survival, although the Earth itself would probably heal and go on as before.

But what if this mini-black hole had too low a velocity to enable it to pass through the Earth and instead became trapped in the terrestrial gravity field? It would then fall towards the planet's centre, overshoot, fall back, overshoot again, fall back again, and so on. Because of the Earth's rotation, however, the oscillation would not be along a single line but along a series of linked tracks. The mini-black hole would therefore carve out an irregular volume from the Earth's interior, growing larger as it did so and absorbing more matter with each sweep. Thus hollowed out, the Earth would probably collapse into the black hole with a diameter of 2 cm and a mass and gravitational field identical to that of the planet it had destroyed.

Fantasy? Possibility? Probability? No, yes, no — in that order. As it happens, mini-black holes, black holes of less than stellar size, have not yet been detected, although they were postulated on theoretical grounds by Stephen Hawking in 1974 and to that extent are a serious scientific possibility. The chance of one of them colliding with the Earth must be regarded as remote, however, if only because if such hole-planet collisions were common there would be far fewer bodies in space than there actually are. On the other hand, annihilation of the Earth by a mini-black hole is only one of a bewildering variety of possible catastrophes, many of them less bizarre than that, through which the human species might meet its end.

Indeed, there are so many possibilities here that in his book about them Asimov has had to design a five-fold classification system in order to make the overall picture intellectually assimilable. To begin with, then, we have "Catastrophes of the First Class", defined as changes such as to

PROGRESS IN MEDICAL ULTRASOUND

reviews & comments

VOLUME 1/1980

edited by A. Kurjak

1980. approx. 340 pages

ISBN: 0 444 90144 2

Price: Dfl. 125.00/US\$ 61.00

or

Dfl. 95.00/US\$ 46.25 if a
continuation order for
1980, 1981 and 1982 is placed

'Progress in Medical Ultrasound, reviews & comments' will provide on an annual basis, comprehensive and critical reviews of the relevant literature found in approx. 3500 medical journals. We will do this fast and we shall try to do it accurately. We shall also speak with authority. By way of elucidation: the reader will find almost 800 references in this book to articles which have appeared in 1978 and in the first half of 1979. All reviews have been written by experts of international reknown.

The chapters provide not only essential new data, but also serve as a guideline to how this literature may be interpreted and what the repercussions may be for medical practice. In other words, this book should inform our colleagues of the information available on the topic concerned, how reliable this information appears to be and what conclusions may be drawn from it. It should be a tool for distinguishing facts from fiction.

A. Kurjak

CONTENTS:

Foreword - A. Kurjak; Introductory essay: Sonar - its present status in medicine - I. Donald; Equipment standardization and imaging testing - B. Breyer; Tissue characterization - C. R. Hill; New techniques - N. Bom and C. T. Lancée; New clinical applications - G. Kossoff; Fetal movements in early pregnancy - E. Reinold; Fetal cardiovascular dynamics - J. W. Wladimiroff; Fetal activity in late pregnancy - K. Maršál; Fetal abnormalities in early and late pregnancy - A. Kurjak; Ultrasonic examination in gynecology - A. Kratochwil; Ultrasonic monitoring of ovarian structural changes - B. J. Hackelöer and S. Nitschke-Dabelstein; Ultrasonic monitoring of ovarian stimulating therapy - S. Nitschke-Dabelstein, B. J. Hackelöer and G. Sturm; Ultrasound - evaluation as a method of choice in the diagnosis of ectopic pregnancy - P. Jouppila; Current status of breast echography - T. Pyrotechnics

Joseph H. McLain

An authoritative survey of all aspects of pyrotechnics, giving practical detail on the composition of a variety of mixes, including military smokes, propellants, primers, flares and common fireworks. Covers the full range of applications, both civil and military.

Ready June \$24.50

Exercise and Sports Sciences Review, Volume 7

Edited by Robert S. Hutton and Doris I. Miller

Topics covered in this volume range from the physiology of swimming man to the biomechanics of overarm throwing movements.

213 pages \$25.00

Enguide: A Guide to Bibliographic Data for Users of Environmental Information

Franklin Institute GmbH

Prepared for the Commission of the European Communities, this useful reference is designed to facilitate access to environmental information from both on-line data bases and those available through conventional channels.

100 pages \$14.95

Dictionary of Biomedical Acronyms

render the whole Universe uninhabitable. One of these — the so-called heat death, by which all non-thermal forms of energy are reduced to heat, and entropy reaches its maximum — is inevitable, although it will not occur for at least a thousand billion years. Equally inevitable, though on an even less certain time-scale, is the contraction of all stellar bodies to black holes and the ultimate coalescence of the whole Universe into a single, huge black hole. And finally there is the possibility that the Universe will contract to the sort of 'cosmic egg' from which it developed via the big bang, although this depends on whether the Universe is open or closed (possibly oscillating).

Inevitable or not, however, all First Class death threats are too far ahead to worry about; they are intellectually interesting but of no practical concern. The same could be said about most "Catastrophes of the Second Class", namely, those able to destroy life on Earth by killing the Sun, leaving the rest of the Universe intact. Ultimately — in billions of years time — the Sun will develop into a red giant and then white dwarf, ending its role as supporter of life on Earth. Moreover, in the shorter (but still very long) term the Sun could be annihilated by collision with a star, a 'normal' black hole or a large body of antimatter (which may or may not exist), all of which in any case should give plenty of warning.

With "Catastrophes of the Third Class", on the other hand, a new factor enters — the possibility (but improbability) of immediate death. An undetected mini-black hole of the type mentioned earlier could even now be about to enter the Earth's atmosphere, interaction with which would give a three-minute warning of the planet's annihilation. But if that sounds alarming, it has to be admitted that most other Third Class changes, defined as those potentially able to destroy all terrestrial life by disturbing the Earth itself, are unlikely actually to do anything of the sort. Collision with extraterrestrial objects (asteroids, meteors etc.), interaction with the Moon, earthquakes, volcanoes, moving plates, glaciation and a disappearing geomagnetic field all can, and do, give rise to local disaster, and some (especially glaciation) could conceivably destroy modern Western civilization; but only in very exceptional circumstances could they obliterate all life, or even all human life.

Which brings us to "Catastrophes of the Fourth Class", or those capable of destroying all human life but not most other life forms. This category includes being overrun by insects or rodents, war, the spread of infectious disease and attack by superior extraterrestrial intelligence, although war (especially thermonuclear) and a hitherto unknown disease (perhaps man-made) seem to be the only two worth worrying about. Perhaps of rather more concern, however, are those activities and

events unlikely to destroy all human life but able, nevertheless, to ruin civilization as we know it — "Catastrophes of the Fifth Class". War again, depletion of natural resources (including energy) and pollution are the chief contenders here.

Asimov is an optimist, evidently believing that those catastrophes possible in the short term are avoidable with intelligent handling, although he warns that success in overcoming them could lead to new dangers such as overpopulation and starvation. Be that as it may, he has left us in the meantime with a remarkable survey of the possible dangers, ranging from the

fascinatingly bizarre to the frighteningly realistic. His book, though by no means short, manages to pack an astonishing number of explanatory asides (on entropy, quasars, red giants, supernovae, DNA, cosmic rays etc.) into a story covering an equally remarkable number of primary disciplines (cosmology, geology, biology, technology etc.). I could quibble a bit over points of presentation, but there is no denying Asimov's explanatory powers. □

Theology after Darwin

A.J. Cain

The Post-Darwinian Controversies. By J.R. Moore. Pp.205. (Cambridge University Press: Cambridge, 1979.) £18.

THE subtitle of this book is "A Study of the Protestant Struggle to Come to Terms with Darwin in Great Britain and America 1870-1900", and indicates its nature far better than the main title. As such, it is not in one sense a book to review in a scientific journal, although *Nature* did publish an exchange of letters between Asa Gray and G.J. Romanes on the religious implications of evolution, in 1883. In another sense, as a study of the intellectual forces resisting, modifying, or encouraging the spread of a particular complex of ideas, it is of interest to everyone.

An idea or complex of ideas is introduced into so heavily structured a space, and engenders such complex reactions, that any account of its spread can only be made, as yet, historically, philosophically or bibliographically. I once consulted a professor of plasma physics on the mathematics necessary for modelling the spread of an idea; he dismissed the subject out of hand as "too hopelessly complicated". And as any historian, philosopher or bibliographer has himself a mind already structured, his account will necessarily be slanted to some extent. Slight slanting is insidious; blatant slanting usually produces a rival account, useful or merely eristic.

James Moore is particularly concerned to do away with the old metaphor of warfare between ideas — the victorious army of the Darwinians, the forces of obscurantism in full flight, the signal victory of Huxley over Wilberforce, and so on. It cannot be denied that there were plenty of people who belonged to neither 'army'; they accepted doctrines of both

camp, and struggled to reconcile them. Two chapters of the book are entitled "Warfare's toll in historical interpretation" and "Towards a non-violent history". These are in Part I, "Historians and Historiography", in which Moore points out the evils of such a schematic representation of extremely complex events. He blames John William Draper (*History of the Conflict between Religion and Science*, 1874) and Andrew Dickson White (*A History of the Warfare of Science with Theology in Christendom*, 1896) particularly for the prevalence of the metaphor in the evolutionary context, giving very useful sketches of their careers and intellectual conflicts to explain both the nature of their books, and the wide difference in scholarship between them. In Chapter 4, "Towards a non-violent history", he brings out his own approach, deploring the use of the military metaphor as showing "the absence of any deep moral aversion from war". Yet he himself allows (as any man of sense must) that "Christians in the late nineteenth century were beset with spiritual disorders and intellectual strife". The metaphor of armies of individuals fighting may be unsatisfactory; at this point the reader might think him about to take up that of gladiatorial combat between ideas within a single individual, which at first sight is nearer the truth. But it is far more useful, as Moore shows, to take a less superficial view. He uses Festinger's theory of the structure of cognitive conflict to show how the individual (merely the arena in a gladiatorial metaphor) is active in reducing the dissonance between incompatible ideas, either by altering one or other idea, or by introducing new ones that reduce the dissonance. He illustrates the point pleasantly by a flat-earthier confronted by an extra-terrestrial photograph of the Earth, and more seriously by the example of that unfortunate man St. George Jackson Mivart. Violence, then, is replaced by the reduction of dissonance — an undoubted gain, but one cannot help feeling that a real baby (incompatibility of ideas leading to real distress) was nearly

thrown out with a lot of bathwater.

Moore gives a useful sketch in Part II, "Darwinism and Evolutionary Thought", of the actual scientific and philosophical issues at work in his period, showing Darwin's difficulties, methodological criticisms, the influence of Herbert Spencer, and the differences that transformed Darwin's Darwinism into neo-Darwinism. (His account of the influence of Paley on Darwin, later in the book, is especially valuable.) Unfortunately, he adopts Morse Peckham's distinction of Darwinism and Darwinisticism — Christian Darwinism "understood Darwin's theory and left it substantially intact, neither emasculating it nor adulterating it with foreign ideas in the interests of dissonance reduction" and Christian Darwinisticism (unpleasing term) "either misunderstood, misinterpreted, or modified Darwin's theory, adulterating it as they had need with non-Darwinian ideas". (Surprisingly, these definitions are not in the index.) It comes as a shock to the student of evolution to find Lamarckism labelled Darwinisticism.

Lastly, in Part III, "Theology and Evolution", Moore makes his most valuable contribution, with sketches of 28 Christian controversialists, American and English, their intellectual predispositions, development and final attitudes. Most are substantial figures, well worth analysing. A few are more reminiscent of Elderess Polly, Elderess Antoinette and Newman Weekes, in Matthew Arnold's bland and devastating account of religion in America. Moore shows that some more orthodox Christians, especially Calvinists, had far less difficulty in accepting natural selection and the struggle for existence as the true cause of evolution than did most liberals, and that much of what has been written on the period shows a complete lack of understanding of Protestant stances.

It would require a far more massive exposition even than Moore's to do justice to these great themes. Moore has much to say on progress, providence and criteria of explanation. Yet his treatment of theological themes omits, rather surprisingly, all useful mention of the Fall, and not too much is said of the creation of Adam and Eve. The theologically orthodox positions he discusses (and the reader is sometimes not clear about *which* orthodoxy he is discussing) are mainly of Dissent; Catholics and Anglicans feature prominently but are not as well analysed as Congregationalists, Unitarians or Presbyterians. A more serious weakness is superficiality in the analysis of some of his characters. For example, Frederick Temple is commended (rightly) for his "generous and incisive" sermon to the British Association the day after the famous encounter of Huxley and Wilberforce, and his *Relations Between Religion and Science* (1885) is quoted as reducing natural selection to "one partial expression" of the

original properties impressed on matter by the Creator. (This, of course, is the old fallacy that if you can write an equation for something, then the equation being devoid of emotions, so should we be in contemplating the thing.) Moore also quotes Aubrey Moore's correct criticism that Temple's attitude although he was an Anglican clergyman (and later Archbishop of Canterbury) was pure Deism, not Christianity. But he does not point out that Temple's *Relations* is one of the worst examples published of using the then ignorance on certain scientific subjects to insist that God must have acted directly in these matters. Huxley's correct criticisms of Lord Kelvin on the age of the Earth disproving evolution by natural selection

are dismissed in quoted words as to be "praised more for their vigor than their strength", although a divine making the same point is referred to without qualification. (It is not always clear whether the book is an analysis of attitudes, in which case it should be more trenchant, or a demography, which requires a greater coverage of people.)

This book is a 'must' for historians of ideas, useful for students of evolution and theology, and quite interesting enough to recommend to the public generally. □

Better buy a pair of climbing boots

Fred Dainton

Scientific Productivity: The Effectiveness of Research Groups in Six Countries. Edited by F. M. Andrews. Pp.469. (Cambridge University Press: Cambridge, UK, and New York; UNESCO: Paris, 1979.) £20.

REMINDED by the title of this book of currently fashionable productivity deals in wage bargaining and on the evidence of a photostat of the title page, the list of comments and the editor's explanation of the purpose of this book, I undertook to myself to review it in a matter of two or three weeks even though I have a rule that all reviewers have an inescapable duty to read every word the author puts before them. I failed in the task not because of any physiological inability to reproduce on my retinas faithful images of the words in front of me nor because of any lack of interest in the subject (wouldn't we all like some philosopher's stone which would enable us to improve the productivity of research units?), nor because of any unwillingness to learn the techniques of the sociologist, so abundantly deployed here, if that were the necessary price of wisdom, but simply because of a great weariness of the flesh induced by perusal of the pages.

As I hacked my way through the verbal undergrowth, pausing to absorb the significance of each of the numerous qualifying clauses, worked my way through complicated diagrams and then re-read in order to make sure that despite all appearances there must be gold somewhere, I longed for the experience, common sense and humanity of a Medawar to tell us in plain words how

scientific productivity can be increased. My prayers were answered for on the 28th February his *Advice to a Young Scientist* was published and happily fell into my hands, and, though this latter book contains no figures, no tables and less than one-fifth of the verbiage of *Scientific Productivity* and is not explicitly directed to this subject, Medawar has far more of value to say to scientists, scientific administrators, and science policy makers and watchers at one-quarter of the cost.

Scientific productivity is a difficult concept, raising questions of volume, intellectual or experimental excellence, magnitude and nature of the impact of the research unit's output on the development of the subject (some developments seen as exciting at the time they are published are later shown to be inhibitors rather than catalysts of progress, a point not really brought out in the book), applicability to economic or social ends etc., etc. Moreover the weight to be attached to each of these many factors might be expected to depend not only on time but on the social and political viewpoint of the assessor. So one has great sympathy with the team of investigators in their methodological difficulties. Therefore the reader tends to concentrate on the conclusions to see if they are so much better and more useful than widely held views and opinions that, as that rock of common sense Ralph Waldo Emerson predicted "The world will make a beaten path to his [in this case the authors'] door". I fear the world will not, for who will want to read so much to arrive at conclusions like the following. I quote from Part 1: "The social position of the individual within the social hierarchy of a research unit proves to be one important correlate of differences in performance at the individual level and the size, age and scientific exchanges of the research unit are additional factors that relate to group productivity", "The results from academic research units seem to be in accord with the 'human relations thesis' that is, that the idea that good leadership

leads to a high group morale and that high morale leads to increased productivity by group members", "that human resources are more significant than [financial resources or access to information]", "The results show that higher levels of effectiveness tend to occur where there is more communication" and "That higher performing units tended to have more dedicated professional members with more diverse working roles and intellectual resources".

But one must have some sympathy for the authors. It seems that a questionnaire, reproduced in an appendix, was sent out to a large number of workers in many European research units. 11,000 of them in 1,200 units distributed over six countries responded. Those who devised the questionnaire are also the authors of the 14 chapters which comprise the book and they had at their disposal all the information elicited by the questionnaires. Apart from the first two chapters (in many ways the best in the book) describing how the International Comparative Study on the Organisation and Performance of Research Units was conceived and mounted and the resultant data analysed, each chapter is by a different author or group of authors. Full freedom was given to each to use his or her own methodology and to exercise personal judgements, and no attempt was made to draw them into a symposium at which differences and common features of their conclusions could be collectively explored. Indeed there seems to have been a perverse pride in avoiding this useful device and also in inexplicably arranging the chapters in an order "alphabetical by the authors' national or international affiliation". I expect that, like myself, other sociologically illiterate scientists would have been grateful to have had some guidance provided by a consensus of the consortium members as to the weights to be attached to the various findings. Nonetheless several chapters do have some useful reviews of past work, and some conclusions are drawn from this and from the empirical data yielded by the enquiry.

It is sadly ironic that the book appears under the imprimatur of Cambridge University where so many highly successful research units have been established either by administrative fiat or more often have evolved from a happy coincidence in time and place of an opportunity and those capable of seizing it. This prompts the questions as to whether Max Perutz, when building up and running the highly successful Laboratory of Molecular Biology in Cambridge, and indeed others with similar track records, would have done better if they had had all these conclusions firmly embedded in their consciousness and, more importantly, whether those charged with the responsibility for establishing units in the future would make better decisions after reading this book. The answers must

remain a matter for conjecture but I am quite certain that they would have been even better advised to read Medawar and then ask themselves a series of questions: for example "Would a research unit in this field offer a reasonable prospect either of a significant advance in knowledge or of meeting some societal need? How can I identify and appoint the highest quality person(s) to lead it and procure the necessary material resources for them? What is the best intellectual environment for the unit to flourish?" And perhaps of greater importance "How can the inevitable tension between the paymaster and the research unit be mediated so as to maximize the freedom of the Director and his staff which is necessary for high creativity and productivity without giving them a licence grossly to ignore the terms of reference under which they operate?" Then there is finally the most difficult question as to how one is to know when the research unit has served its purpose or has lost its quality and should be closed. There is little in this book which helps with the resolution of these practical problems and what there is is difficult to quarry without reading the whole book for there is no subject index.

Of course this is not the only book which fails such tests of practical utility to the decision makers but which may nonetheless be of value to the community of scholars to which the authors belong, in this case all those interested in sociological enquiry. I am not competent to express any opinion on this latter question, and in any case this is perhaps of less relevance because the Foreword by UNESCO makes it plain that the work was the outcome of that body's Nineteenth General Conference and the same Foreword refers sympathetically to "... citizens in many countries asking for more public accountability. They want to know the use to which their resources are put and they demand that the programs that they support shall be both efficient and effective". That these desires should be gratified is unexceptionable. This principle can equally be applied to the UNESCO programme of which this book is the visible and ponderous product. All the more pity that we are not told how much the whole enterprise cost and thus be able to judge whether the expenditure was justified. I have a strong feeling that if those scientific directors of research units who spend £20 on this book were each to buy, at slightly greater cost, a pair of good mountaineering boots and, after salubrious daily scrambles, to confer on this topic in the evenings throughout a week spent at some delectable Alpine centre they would bring down from the mountain more useful tablets than this book. □

Coats of many colours

Anne McLaren

The Coat Colors of Mice. By W.K. Silvers. Pp. 379. (Springer: Berlin, Heidelberg and New York, 1979.) DM59.60, \$32.80.

SOME targets of scientific study are inherently attractive. One such is soap bubbles. Another is coat colours and patterns. In the days when I knew R.A. Fisher, the father of modern statistics, his true pride and love was for mouse genetics, and to be asked the effect of umbrous on an agouti pink-eyed brown background would really make his eyes twinkle.

W.K. Silvers' book is also a labour of love. There is no mention of Sturtevant's intriguing suggestion that Mendel discovered his 'laws' of segregation and assortment by illicitly crossing different-coloured mice in his monastery cell, later using his curiously exact pea ratios as a mere didactic demonstration; but in other respects the early history of the subject is well covered. The references include more than 20 papers published in the first two decades of this century on the genetics of coat colour in mice, starting with the classic 1902 paper of Cuénot. One of these pioneers is still living, Naomi Mitchison, who, with her brother J.B.S. Haldane, published in 1915 the linkage between albino and pink-eyed dilution, the first to be established in any mammal. A start was also made in those early years on the chemistry of mouse pigmentation (Onslow, 1915) and on the developmental analysis of lethal yellow (Ibsen and Steigleder, 1917), while C.C. Little's life-long interest in mouse spotting genes gave rise to a series of papers beginning in 1913.

Moving to more modern times, Silvers pays tribute to Grüneberg's monumental *Genetics of the Mouse* (Nijhoff: The Hague, 2nd edition; 1952), to Searle's *Comparative Genetics of Coat Colour in Mammals* (Logos Press: London; 1968), to Mintz's illuminating studies on experimental chimeras ('allophenic' mice) and to the great amount of assistance that he received from Rita Phillips, whose very recent death is a sad loss to mouse genetics as well as to her many friends and colleagues.

Apart from its aesthetic appeal, the study of coat colours embraces not only genetics (148 alleles at 63 loci), but also biochemistry, cytology, histology, anatomy, embryology and endocrinology. Silvers does justice to all these aspects. The first half of the book, in which he deals with the various colour-controlling loci and their complex interactions, is perhaps more satisfactory than the second half, which covers spotting genes, chimeras and X-chromosome mosaics. The etiology of

spotting and coat colour pattern is still widely debated, and even the experimental evidence is sometimes conflicting. Silvers does his best to summarize the literature, but the picture that emerges is patchy in more senses than one. For example, in the field with which I am most familiar, he perpetuates confusion by failing to make clear that Mintz's 'standard' or archetypal pattern is a valuable abstraction rather than an observed pattern ('observed relatively rarely' is misleading when the true probability, for one side of the mouse alone, is 2^{-16} , less than 1 in 100,000); he does not mention Lyon's interesting suggestion that the frequent brindled sectors of chimeras arise because each territory may be colonized, not by one but by two 'primordial melanoblasts', of the same or contrasting genotype; and he affords the same status to the clonal theory of pattern formation for hair follicle chimeras as for melanocyte chimeras, though the evidence is far less cogent for the former than for the latter.

But these are minor grumbles. The book as a whole will be a standard reference work in every mouse genetics laboratory for many years to come. Not only does it make admirably clear the complex interplay of genetic (and in some cases environ-

mental) factors in determining coat colour, but it also uncovers areas where further research is badly needed. These include spotting genes, of course; the intriguing behaviour of silver, resembling the effects on pigmentation of irradiation, and perhaps also ageing; the 'reds' of the mouse fancy, and no doubt other fancy types also, not yet analysed genetically; and, above all, the need for a codification of colour, a decent set of colour standards, which although doubtless imperfect could hardly but improve on such phrases as "a dull brown colour", "a medium shade of sepia", "a faint cream or ivory color", "a brownish shade, a little lighter than an ordinary pink-eyed brown with a slight dull yellowish cast". The three colour plates in the present volume are not of very high quality, though better than nothing; really good colour reproduction would have presumably escalated the price unacceptably.

As it is, the book at about £15 is reasonably priced, there are good author and subject indexes, and the bibliography is comprehensive. □

Anne McLaren is Director of the MRC Mammalian Development Unit, London, UK.

The classic electricians

W.D. Hackmann

Electricity in the 17th and 18th Centuries. By J. L. Heilbron. Pp. 606. (University of California Press: Berkeley, Los Angeles and London, 1979.) £24.

AN ambitious work that deserves to become a classic in this subject. Not only has Professor Heilbron incorporated all the historical papers on early electricity that have appeared since I. B. Cohen's *Franklin and Newton An Inquiry into Speculative Newtonian Experimental Science and Franklin's Work in Electricity as an Example Thereof* (The American Philosophical Society: Philadelphia, 1956), but he has also included much new material, such as the importance of the seventeenth century Jesuit polymaths in the study of physics in general, and in electricity in particular. For those of us reasonably well versed in this subject, the main developments as given in this book are known, but it is useful to have such a broad and up-to-date survey. The general reader interested in the history of physics, or of electricity, should find this a fascinating story, although he might miss some of the finer philosophical or technical nuances. Any historical treatment of a scientific subject must contain inevitable

distortions as all is focused on specific aspects of the total picture, but by attempting such a broad canvas, Heilbron has managed to keep these distortions to a minimum.

A work of this nature, covering such a large time span, is inevitably faced with historiographical problems. Terms and concepts change their meaning, brought about by new discoveries and by changes in philosophical outlook, and this makes interpretation difficult. The author has to make it clear to the reader that a problem dealt with in the seventeenth century was handled differently from the same problem looked at by physicists one hundred years later. When surveying a subject over a very long period, it is possible to give it a false appearance of continuity, while the subject progressed (or changed) in a much more convoluted manner. In the context of this book, both the concepts of physics and of electricity changed dramatically during these two hundred years. The word 'electricity' was to undergo subtle changes in meaning during the century after its use by Sir Thomas Browne in his *Pseudodoxia Epidemica: or, Enquiries into very many received tenents and commonly presumed truths* (1646), causing endless confusion to historians of science in the past. At first it simply referred to the attractive property of amber and other substances. The word only began to denote a separate entity or substance causing the electrical behaviour of attraction and repulsion during the early 1740s. Heilbron has coped admirably with this kind of problem, not least by the way

new books from Blackwell

The Ecology of Fresh Waters

Brian Moss. April 1980. 348 pages, 95 illustrations. Paper, about £9.50

The author's infectious enthusiasm for his subject is clearly evident in this book, and this, together with his lively style of writing and the numerous informative illustrations, combines to provide students with a stimulating introduction to freshwater ecology. It is an attractive text on an area of applied biology that is becoming of increasing importance.

Essential Reproduction

M.H. Johnson and B.J. Everitt. June 1980. 376 pages, 137 illustrations. Paper, about £6.50

This stimulating text provides an integrated approach to the study of mammalian reproduction covering anatomical, physiological, genetic, biochemical and behavioural aspects. It includes discussion of all aspects of male reproduction, female cyclicity, pregnancy, post-natal care and fertility control and is designed as a lucid introduction to the student.

Introduction to Modern Virology

Basic Microbiology Volume 2, by S. B. Primrose and N.J. Dimmock. Second Edition, May 1980. 264 pages, 148 illustrations. Paper, about £7.50

Studies in Microbiology

An important new series, edited by N.G. Carr, University of Liverpool, S.C. Rittenberg, University of California, Los Angeles and J.L. Ingraham, University of California, Davis

Volume 1

Developmental Biology of Prokaryotes

Edited by J.H. Parish. 1980. 310 pages, 93 illustrations. £19.00

The prokaryotes form the most ancient lineage of organisms on the earth. They have a wide variety of habitats and play a central role in the fixation and turnover of nutrients. Like higher organisms, prokaryotes demonstrate a variety of developmental changes which are central to an understanding of their physiology, ecology and behaviour. This book, the first volume in the *Studies of Microbiology* series, reviews the developmental biology of major groups of prokaryotes and also attempts to diagnose developmental changes in terms of molecular processes.

Immunology at a Glance

John H.L. Playfair. 1980. 86 pages, 35 illustrations. Paper, £2.25

'The whole provides as neat and clear an introduction to this rapidly evolving and intricate discipline as the non-specialist could wish for. A valuable contribution to doctors, medical students, and indeed all acolytes of biology.' *World Medicine*

'It is a good book, based on a novel approach.' *Nature*

Neuroethology: an Introduction

D.M. Guthrie. Summer 1980. 320 pages, 171 illustrations. Paper, about £7.50

This book brings to the attention of undergraduates the recently expanding area of interaction between neurobiology and behaviour. Examples are taken from neurobiology only when they are directly relevant to studies on ethology. This rules out much pure neurobiology, and leads to a slight bias towards vertebrate studies.

Insect Physiology

W. Mordue, G.J. Goldsworthy, W.M. Blaney and J.N. Brady. June 1980. 124 pages, 71 illustrations. Paper, £5.75

Volume 2

Principles of Gene Manipulation: an Introduction to Genetic Engineering

R.W. Old and S.B. Primrose. 1980. 152 pages, 49 illustrations. Cloth £10.00, paper £5.50

This book describes the basic principles behind the subject popularly known as genetic engineering, an area of biology that is advancing so rapidly that many scientists find it impossible to keep pace with the current rate of progress. However, some important techniques have now become established and it is therefore anticipated that this introduction will not date too quickly. It is designed to provide advanced undergraduates and those already working in biological research with a simple guide to enable them to follow the current literature and future developments. The authors have developed the book from a successful course on gene manipulation for students of biology, microbiology and biochemistry, and this concise but lucid text should give its readers a firm understanding and interest in the subject.

he has structured this book, which he has divided into five parts.

Part 1 sets the scene by giving a general survey of early modern physics, its underlying principles and the ways in which it was diffused, including the founding of scientific societies, the development of better instruments and the importance of lecture-demonstrations. He divides some 210 electricians (as those studying this subject called themselves) into five groups according to their chief means of support: members of religious orders (especially Jesuits), paid academicians, professors, public lecturers, and others (primarily instrument-makers, doctors, lawyers, clergy and the independently wealthy). Between one-quarter and one-half were professors of universities or secondary schools. It is difficult to determine how approximate these figures are. They contain overt generalizations (of which the author is aware), and there are inevitably minor inconsistencies and errors. For instance, in the table dealing with the number of academies founded between 1660 and 1800, he lists no provincial societies under Britain (apart from one by name), while under 'others' in the case of France, he lists 27, and under Holland 14 (these include agricultural societies). This produces a distorted and not very meaningful picture. In general, however, his conclusions are justified.

Part 2 surveys the progress of electricity during the seventeenth century, starting with Gilbert's experiments on the amber effect in *De magnet* (1600), terminating soon after Otto von Guericke's experiments with his 'globus mineralis' in the 1660s. Part 3 covers the first half of the eighteenth century, starting with the researches of Hauksbee the elder, at the Royal Society during the early 1700s. Part 4 deals with the impact of the Leyden jar (a primitive condenser), discovered in 1745, and the reception of the theories of Benjamin Franklin. Part 5 covers the last thirty years or so of the eighteenth century, during which the main electrostatic principles were finally formulated and attempts were made at quantification. This period is terminated with an Epilogue describing the invention of the voltaic pile or battery in 1799. During the entire two hundred years, 'electricity' meant electrostatics, then known as 'frictional electricity', as it dealt with charges generated by rubbing glass or other electrics.

The sub-title, "A Study of Early Modern Physics", is significant, for the author has tried to relate the history of electricity to the broader conceptual changes that occurred during the rise of early modern physics. Effectively, he has divided the history of this subject into three stages. The first stage, which lasted until 1700, was still dominated by Aristotelian physics, a textbook science which included organic and psychological as well as inorganic phenomena. The second stage, lasting until

Wilson's public model lightning conductor experiments at the Pantheon, London, 1777.

the 1750s was dominated by the followers first of Descartes, and then of Newton. The Newtonians, who by their virulent empiricism had taken Newton's "hypotheses non fingo" much further than had been intended by their master, gained the upper hand during the 1720s. Physics took on a more restrictive and modern meaning; the subject now being restricted to astronomy and experimental physics (alternatively known by the vague English term of natural philosophy), which included mechanics, hydrostatics, pneumatics, optics, electricity and magnetism, but excluded subjects such as psychology, medicine and the biological sciences. The importance of applied mathematics in the formulation of physical laws began to be stressed, amongst others, by 's Gravesande, but this approach only gained momentum during the third and final stage. Heilbron points out that the advances made in quantifying electrical phenomena from the 1760s onwards owed nothing to the progress of mathematics. Indeed, not until the turn of the nineteenth century did electricians require mathematical techniques not fully available a hundred years earlier.

In order to make progress in electricity, required were (1) carefully worked out experimental procedures which could be replicated by different physicists, (2) accurate and reliable instruments, and (3) the isolation from the mass of experimental details of those factors that were important in producing the observed phenomena. Heilbron's narrative demonstrates how the conflicting data took many years to untangle. These three requirements are, of course, interrelated. Nature was often 'manipulated' in those areas in which new phenomena were expected. Attempts to store charge and to electrify water resulted in the discovery of the Leyden jar by von

Kleist in Germany, and Cunaeus and Van Musschenbroek in Holland, although the results were unexpected and went far beyond the experimenters' expectations. Incidentally, Heilbron honours Cunaeus with this invention, but this claim cannot be substantiated. Simultaneous and independent discoveries of this nature usually signify that the conceptual framework and experimental techniques have become available for these breakthroughs to be made.

Heilbron is fully aware of the importance of the Leyden jar. It led to the study of more powerful electrical phenomena, and it assisted with the formulation of new concepts such as that of electric circuit, intensity or level of electrification (an anticipation of potential), capacity or area of coated surface electrified, and quantity of charge, for it could readily be compared with the behaviour of liquids flowing from vessels of different sizes. The invention of the electrophorus (1775) and the parallel plate condenser (1778), based on the Franklinian explanation of the Leyden jar, not only strengthened the formulation of these concepts, but also focused on minute electrical charges (Volta's 'contact electricity'), which eventually led to the invention of the voltaic pile. Early attempts to explain this remarkable device in terms of standard electrostatic theory based on the Leyden jar failed, and it did not take long for scientists to realize that other concepts such as current intensity and electrical resistance were necessary. Thus, instruments influenced the formulation of new concepts, and the latter in turn affected instrument design. Although his conclusions are broadly in agreement with this view, Heilbron's general discussion on the development of electrostatic instruments is weak, and contains minor factual

Globe machine with suspended boy conductor, 1748.

errors.

Quite properly, Heilbron devotes an entire chapter to electrometry. He discusses the key electrometers, especially those of Robison (1770s) and Coulomb (1784). One does not, however, become aware of the existence of the great number and diversity of electrometers invented during the final decades of the eighteenth century, caused by the search for

replicability of measurements. Attempts to standardize measuring techniques and introduce electrometric standards prior to Coulomb's work failed, mainly because there was no proper understanding of what the different electrometers were actually measuring. According to Heilbron, what was lacking was the appreciation between the difference of electrostatic force at a macroscopic level (moving force or kinetic

energy), and an (idealized) microscopic force as an unobservable push or pull between elements of electrostatic charge. The triumph of Newton's theory of gravitation was to compute force by summing forces, but this distinction was not generally understood by physicists before the second half of the eighteenth century. Modern historians of science, too, have not always made this distinction when interpreting the early attempts by Bernoulli (1760) and others to relate the behaviour of electrostatic force to the inverse-square law of gravitation. Robison, Cavendish and Coulomb were the first to achieve this. They were the vanguard of a new breed of physicist, unlike their predecessors more interested in exact mathematical descriptions than in the qualitative models which had played such an important role in the early history of electricity. They formed the bridge between the qualitative work of the preceding two hundred years and the mathematical synthesis by Poisson and others in the nineteenth century. □

W.D. Hackmann is Assistant Curator of the Museum of the History of Science at the University of Oxford, UK. He specializes in eighteenth century history of science, especially electricity and Dutch science.

Plasmid horizons

Naomi Datta

Plasmids. By Paul Broda. Pp.197. (Freeman: Oxford and San Francisco, 1979.) £6.90, \$18.50.

RESEARCH on plasmids is exciting and varied. It includes intensive study of very basic biological functions such as DNA replication. F-mediated conjugation provides an example of differentiation of structure and function in a single-celled organism, subjected to detailed genetic analysis. Insertion sequences and transposons are newly discovered and evidently important means of genetic variation allowing evolutionary changes in response to changing environment. Plasmid-determined antibiotic resistance and determinants affecting bacterial virulence are of great medical relevance, and study of the latter, in particular, may lead to new insights into bacterial pathogenicity. Plasmid synthetic and degradative enzyme systems, evolving all the time, are likely to be of increasing commercial and environmental importance. And, as well as all these reasons for the study of plasmids as they exist in nature, their use as vectors in genetic engineering opens up new horizons in biological research both academic and pragmatic. No wonder that the number of papers published on plasmids seems to be increasing exponentially. An up-to-date, comprehensive and comprehensible guide to the subject was badly needed by

undergraduates or research workers starting out in this field. Here it is — Paul Broda has provided just the thing, and it is not only newcomers to the subject who will welcome his *Plasmids*. Plasmid research has its own specializations, broadly on the lines of the subject-matter of the different chapters of this book, and people knowledgeable about any one of them cannot hope to keep up with all the others.

This is a short book, only 148 pages of text excluding references and index, and I was surprised at the amount and variety of detail packed into such a small space. The layout is organized imaginatively to assist a reader to grasp principles with which he may not be previously familiar. The many summarizing tables inserted in the text are particularly successful both as teaching aids and for quick reference. After a brief introduction to define the subject and sketch in its short history, we are presented in a thoroughly practical way with the methods used for isolating plasmids from their host cells. These methods are of two main kinds, either on a fairly large scale to obtain plasmid DNA for further study, or rapid and small-scale, adaptable to many experimental purposes. Great advances in methods of both these kinds have been made in the last few years. It is appropriate that this section should come early on in the book since much of the information on plasmids in later chapters has resulted from the use of these methods.

The chapter on the structure and evolution of plasmids illustrates how those creatures have developed by connecting as well as by diverging evolutionary paths. The use of endonucleases is described, in the characterization of plasmid DNA and also for the construction, *in vitro*, of new plasmid molecules. This implies a very broad meaning for 'evolution', but why not?

The complex subject of DNA replication is considered in Chapter 4. Plasmids are more accessible to experimental manipulation than are whole cells and therefore plasmid replication has been studied, not only for its own sake, but also to elucidate host mechanisms for, and controls over, DNA replication. This chapter covers both plasmid-determined and host functions and throws considerable light on a confusing area of research. Here, as elsewhere in the book, the limitations of current knowledge are pointed out. It is a comfort, sometimes, to be told that something is still unknown.

Transfer of DNA by conjugation in bacteria is, as far as is known, always plasmid-determined. The chapter on the subject summarizes the results of detailed investigations into the conjugative functions of F and its relations, and indicates how little is known about conjugation determined by many other, unrelated, plasmids. It is possible that the production of pili is a prerequisite for conjugation despite the instance, cited on p. 97, where they were apparently not essential. This case referred to plasmids of

Oxford Books for Students

Problems and Solutions in Logic Design

D. Zissos

This book makes easy and reliable logic design techniques available to those with no specialist knowledge of mathematics or engineering: the emphasis throughout is on optimal, rather than strictly minimal designs, which have become less important with the availability of integrated circuits. For the second edition the text has been carefully checked and revised. It contains a new chapter on pulse-driven circuits, and many new problems and solutions. Second edition illustrated £10 paper covers £4.95

Engineering Mechanics

J. M. Prentis

This textbook provides a complete account of vector mechanics for the absolute beginner, assuming only a knowledge of elementary calculus, while maintaining the interest of the reader with previous experience by setting the exposition firmly in the context of engineering. It covers all the basic mechanics a degree student needs to know. The coverage of principles is comprehensive; applications are selective, with emphasis on the relation of principles to practical situations. £15 paper covers £6.95
Oxford Engineering Science Texts

Lectures on the Electrical Properties of Materials

L. Solymar and D. Walsh

These lectures stress the fundamental ideas relevant to the understanding of the electrical properties of materials. The topics are selected so that the operation of devices having applications (or possible future applications) in engineering can be explained. The mathematical treatment is kept simple, and topics that the student finds difficult to follow are carefully explained. For the second edition the text has been revised and updated throughout. Second edition £14 paper covers £6.95

Electronics for Technicians

R. Hamilton

This book introduces students to the electronics principles used in light-current electrical engineering with particular relevance to communications and industrial electronics. It then develops these principles to the level needed for Technician Certificates and Diplomas in a range of specialisms in electronics and communications engineering, covering the objectives developed for this purpose in the TEC standard units at Levels II and III. £12.50 paper covers £4.95
Electrical and Telecommunications Technicians Series

Coulson's Valence

Revised by Roy McWeeny

This well-known textbook had an enormous impact on chemistry when it was first published in 1952. It has now been completely revised and includes exercises, discussions of recent molecular-structure calculations, treatments of chemical reactivity theory, Woodward-Hoffmann and Evans-Dewar rules, expanded sections on the solid state, and a simple introduction to semi-empirical self-consistent field theory. SI units are used throughout. The book is written for chemists, and every effort has been made to preserve the breadth, simplicity, and clarity of the original. Third edition £17.50 paper covers £8.50

Principles and Problems in Physical Chemistry for Biochemists

Nicholas Price and Raymond Dwek

Many of the improvements incorporated in this new edition of this textbook have been based on comments and suggestions from users of the first edition, published in 1974. Chapters 1 and 10 have been completely rewritten; there is a new chapter on macromolecules and a new chapter on ultra-centrifugation. Twenty new figures have been added. Second edition illustrated £8.95 paper covers £3.95

Graphs and Networks

Bernard Carré

This book presents the basic results and techniques of graph theory and network flow theory, with strong emphasis on their applications and algorithmic aspects. It is suitable for final-year undergraduate and graduate students in mathematics, computer science, engineering, and operations research, and it will also be of interest to professional workers in these fields. The presentation is informal but systematic, and all the results given in the body of the text are justified. £14 paper covers £7.50
Oxford Applied Mathematics and Computing Science Series

Energy in the Developing World

The Real Energy Crisis

Edited by V. Smil and W. E. Knowland

Developing countries are the ones facing a real and deepening energy crisis. 'Crisis' for the Western world may mean just a reduction of predominantly wasteful practices and a lowering of expectations, but in the Third World the energy crisis is a matter of economic survival. This book of readings provides a comprehensive review, analysis, and summary of energy in the developing world. £15 paper covers £6.95

Oxford University Press

SCIENTIFIC AND MEDICAL DIVISION MACMILLAN PUBLISHERS

Growth without Ecodisasters?

Edited by **Nicholas Polunin**

President of the Foundation for Environmental Conservation

Spring 1980; £22.50; 695pp; ISBN 0 333 23551 5

This work comprises the 18 keynote papers and the discussions which followed them which were presented at the Second International Conference on Environmental Future held in Reykjavik in 1977. The result is a lively but distinguished attempt to force awareness of the vital need for concerted action if both Man's life and Nature are to survive in anything like their present form.

READERSHIP: Environmental scientists and students, ecologists, conservationists, general readers interested in the future of the environment.
LEVEL: P, G, U, GR (FOR KEY SEE BELOW)

Urban Air-Pollution Modelling

Michael M. Benarie

Head of the Department of Air Pollution, National Institute for Chemical Research, France.

Summer 1980; £30; 284pp; ISBN 0 333 23391 3

This monograph collects together the methods, models and formulae used for estimating air pollutant concentrations in urban areas. The purpose of this work is to assess the aims and the usefulness of the available methods and to show that urban modelling is not just a gaussian plume, but a combination of complementary approaches and possibilities.

READERSHIP: Civil engineers, meteorologists, urban planners and administrators, environmentalists.
LEVEL: P, G, U.

The Fast Breeder Reactor. Need? Cost? Risk?

edited by **Colin Sweet**

Senior Lecturer in Economics at the Polytechnic of the South Bank.

Summer 1980; £17; 208pp; ISBN 0 333 27973 5

This work explores some of the major implications of fast breeder technology. The energy policy relating to nuclear power and the possible alternatives to nuclear energy are discussed in the first section followed by an appraisal of the risks involved in fast breeder technology. The economics of nuclear power and coal are compared and the various options that nuclear power offers for the future are discussed. An interesting section on nuclear power and civil liberties is also included.

READERSHIP: Engineers and scientists involved in energy planning, economists, general readers interested in the 'nuclear debate'.
LEVEL: P, G, U, GR.

Cardiovascular System

Edited by **R. Shanks**

Professor Clinical Pharmacology, Queen's University, Belfast.

Summer 1980; £10; 106pp; ISBN 0 333 28604 9

This work contains a selection of articles first published as a monthly series in The British Journal of Clinical Pharmacology. The articles describe the main methods for the investigation of the effects of drugs on the cardiovascular system in man. All the main aspects of the cardiovascular system are covered including cardiac function and the peripheral circulation with separate chapters being devoted to different methods for examining the same basic function.

READERSHIP: Pharmacologists and clinical pharmacologists, cardiologists.
LEVEL: P, G, UR.

The use of alternatives in Drug Research

Edited by **Andrew Rowan**

Assistant Director, Institute for the Study of Animal Problems, Washington DC and Carl Stratmann, formerly Scientific Consultant for the Fund for the Replacement of Animals in Medical Research (FRAME).

Spring 1980; £8.50; 224pp; ISBN 0 333 27014 2

This volume, based upon a symposium organised by FRAME, has been prepared to consider some of the alternatives to animal use in the specific field of drug research. The eleven papers presented here range over many aspects of the issue. Taken together they provide a valuable focus for discussion and by identifying specific topics for future research this work should help to lead to a greatly reduced use of animals in drug research.

READERSHIP: All research workers in the Biomedical Sciences who undertake any experimentation on animals using drugs.
LEVEL: P, G, UR.

Enzyme Inhibitors as Drugs

Edited by **Merton Sandler**

Professor of Chemical Pathology, Bernhard Memorial Research Laboratories.

Summer 1980; £25; 250pp; ISBN 0 333 28984 6

A new volume in the Biological Council's Drug Action Symposia series, this work covers the developing links between enzymology and pharmacology and the rapidly expanding new field in pharmacology which results from these links. The contributors are leading international authorities in this field and the topics covered included the key subjects of research and debate.

READERSHIP: Enzymologists, immunologists, and pharmacologists.
LEVEL: P, G, UR.

KEY: P = professional; G = graduate; U = undergraduate; UR = undergraduate reference; GR = general readers.
For further details contact Frances Roach, Scientific & Medical Division, Macmillan Publishers, Houndmills, Basingstoke, Hampshire RG21 2XS.

group N whose pili have only recently been seen (Bradley, *Plasmid 2*, 632-636, 1979). The chapter on plasmids in human and veterinary medicine gives an overview of the astonishing evolutionary phenomenon of antibiotic resistance. Very often, within a few years of the introduction of a new antibacterial drug, bacteria resistant to that drug have appeared, the resistance being plasmid-determined. The author points out (p. 138) that the molecular events leading to the appearance of new resistance plasmids may be rare, the intensity of selection for resistance making their effects quickly evident. Gentamicin resistance, for example, is already more frequent in both Gram-negative and Gram-positive bacteria than it was at the time of publication of the papers cited on pp.114-115 of this book, a result of the widespread use of gentamicin in hospitals.

The same chapter also reviews what is known of plasmids that confer pathogenicity. There is reason to hope that research on naturally occurring plasmids, and on plasmids used as cloning vehicles for 'pathogenicity' genes, will extend our present very limited understanding of the effects of bacterial infections.

A chapter entitled "Other Plasmids" describes those determining colicinogeny, degradative functions in pseudomonas, plant tumour causation by *Agrobacterium tumefaciens*, and antibiotic production and resistance in actinomycetes. Obviously, in such a short space there must be much abbreviation and some simplification, and indeed this applies to the whole book. The references, however, are well chosen (the method of choice is explained in the preface) and numerous enough to help the reader to find out more about any of the topics covered in the text.

I have not found many errors in this book and those I have detected are fairly trivial. (To give one example, the semi-synthetic penicillins resistant to staphylococcal penicillinase are described as "cloxacillins" — they should be called isoxazolyl penicillins, of which cloxacillin is one example.) Also, considering the size of the book, I have found very few omissions. The only mention of plasmids in strictly anaerobic bacteria is that referring to *Bacteroides ochraceus* (p. 139); plasmids in *Clostridium* species as well as bacteroides might have been mentioned in Chapter 6.

Two previous single-author books on plasmids are *Bacterial Plasmids* by G. G. Meynell (Macmillan, 1972) and *Infectious Multiple Drug Resistance* by S. Falkow (Pion, 1975). Both are good books but neither, in 1980, can provide for the readers who will, I believe, gratefully welcome Broda's book. □

Towards enlightenment in radioactivity

Thaddeus J. Trenn

Radioactivity in America: Growth and Decay of a Science. By Lawrence Badash. Pp. 327. (Johns Hopkins University Press: Baltimore and London, UK, 1979.) £11.50.

THE value of history may well lie in the perspective the past can provide for the present in its relation to the future. Radioactivity is often talked around today, but generally with little understanding. Radioactive rain and snow were present long before such phenomena were discovered and investigated scientifically. Primitive man had a great fear of lightning and other forces of nature, yet with respect to radioactivity most of us still stand today as did the Neanderthals. Knowledge is power but ignorance breeds impotence. The first step to correct this source of insecurity and fear is to learn what makes it 'tick'. To this end it would be valuable to trace the historical development of man's understanding of radioactive phenomena in a manner accessible to the layman. This is what the book under review has done and why it is so important.

The science of radioactivity had a long and complex history, starting with Becquerel's discovery of natural radioactivity in 1896 and reaching to the discovery of artificial radioactivity by Joliot and Curie in 1934. A spate of major tomes, from about 1930, attests to the maturation of this multi-faceted discipline: Meyer and Schweidler, *Radioaktivität* (1927), Kohlrausch, *Radioaktivität* (1928), Rutherford, Chadwick and Ellis, *Radiations from Radioactive Substances* (1930), Curie, *Radioactivité* (1935), and regular reports on the subject which appeared until 1943 published in the *Annual Reports on the Progress of Chemistry*.

Badash narrows the subject both in time and in range by focusing upon what radioactivity research there was in America from scientists such as Boltwood, McCoy, Baskerville, Bumstead and Pegram. Rutherford and Soddy naturally play a central role not only because they were in Canada when they provided the theoretical explanation of radioactivity in 1902/3 — see *Nature* 274, 723-724; 1978 — but also because they attracted many research workers. Indeed, part of the decline of this American scientific specialty can be attributed, as Badash suggests, to the transfer of these two scientists to the other side of the Atlantic (Chapter 18).

Much of radioactivity research in America was directed towards a clarification of the genetic connections within the several radioactive decay sequences. Such radiochemical analysis fell

in between physics and traditional chemistry and could never really establish itself in America. According to Badash, this scientific specialty was also "suicidally successful" (p. 152); it was no longer viable once the genetic connections had been sorted out in uranium, thorium and actinium. The main lines of radioactivity research thus remained in Cambridge, Paris, Rome and Vienna, leading to artificial transmutation and artificial radioactivity. Even radiochemistry took on a new life as radioactivation analysis (see Broda, *Advances in Radiochemistry*, Cambridge University Press; 1950). In retrospect, we can mark the transition from radioactivity to nuclear physics and nuclear chemistry with the discovery of the neutron in 1932 followed soon after by Fermi's explanation of β -decay.

Badash does not always restrict his historical account of radioactivity to the scientific specialty which had its "growth and decay" in America. When dealing with the concept of isotopy and the group displacement laws, for example, Badash leaves the American scene for two full chapters with the centre of action in Europe. He is overtly sympathetic with Fajan's electrochemical approach, an alternative which phenomenologically did yield nearly the complete and correct formal scheme, although it was unsound (p.211) and accordingly lacked the explanatory power of Soddy's subsequent analysis, for which he alone received the Nobel Prize.

The decline of radioactivity research in America by the end of the Great War was conditioned by factors besides the loss of Rutherford to Europe, the lack of any institutional framework and the self-fulfilment of the goals of this scientific specialty. Radioactivity research "shared the same . . . poverty as other branches of science" in America (p.271). Therefore, what Badash has termed the "decay of a science" is perhaps simply the decline of a scientific sub-discipline as but one more manifestation of a general atrophy or perhaps the "immaturity" (p.274) of American science needing the fertilizing immigration of the 1930s to develop.

The reader may consider much of this somewhat remote from the current pressing concerns about nuclear reactors and atomic bombs. Nevertheless, all this began with radioactivity; the emission of radioactive radiations and the self-transmutation of one isotope to another being nuclear processes. That nuclei can also fission into larger fractions, and that under certain conditions this fission process can lead to a chain reaction are also natural phenomena that need to be better understood. Even scientists were surprised to learn recently that our technological 'eighth wonder' — the controlled fission reactor — had been anticipated by nature when dinosaurs still roamed the earth. Inherent checks and balances prevented this natural reactor from exploding like an

atomic bomb, since the critical state, once reached, tends to turn itself off. The very heat generated by the onset of an uncontrolled chain reaction tends to liquefy the dense and compact solid substance dispersing it, perforce eliminating the concentrated condition so essential for the onset and continuity of the critical state within a mass of fissile material.

Only if a chain reaction can be achieved and executed nearly instantaneously by intentionally overcoming the barriers nature has set can the 'atomic-bomb' effect be realized. The concentration of fissionable material in a nuclear reactor is not appropriate for this effect. In so-called thermal reactors using the isotope U-235, fissile to *slow* neutrons (neutrons of relatively low energy which have been 'moderated' to 'thermal' velocities), the chain reaction of the nearly instantaneous type required for the 'atomic-bomb' effect simply cannot occur. For the same reason, an atomic bomb consisting solely of the rare isotope U-235 would only fizzle. It is

natural uranium, U-238, which provides the main contribution to the 'atomic-bomb' effect, since it can be fissioned with neutrons which are *fast* enough to yield a chain reaction having the required celerity. Once these and other consequences of nature's inherent control mechanisms become better known, there will be less public obsession with the alleged dangerous proliferation in the supply of U-235 and allied (*slow*-neutron) fissile substances like plutonium.

Yet, to have expected the present work to deal with the totality of our misunderstanding about radioactivity and its nuclear progeny would be unreasonable. The scales can be removed from the public perception only in gradual stages. That Badash has taken us a significant step forward is perhaps a sufficient achievement.

Thaddeus J. Trenn is affiliated to the Max-Planck-Institute in Munich, FRG.

Astronomical oddities

Paul Murdin

Monsters in the Sky. By Paolo Maffei. Translated by Mirella and Riccardo Giacconi. Pp.241. (MIT: Cambridge, Massachusetts, and London, UK, 1980.) \$15.

THE monsters in the title of this book are not constellation figures, inhabitants of UFOs, dragons or other overtly mythical creatures. Monsters is used in the same sense as in the section of the *Thesaurus* called Unconformity, where it is associated with wonder, curiosity, missing link and queer fish. The "monsters in the sky" are thus unusual astronomical objects. They are the objects, says Paolo Maffei, which were better left out of his previous book, *Beyond the Moon*, on the more straightforward parts of astronomy, because they were so unusual that they were confusing. The present book assumes the elementary knowledge of astronomy contained in the previous one and builds on it to give accounts of black holes, quasars and active galaxies, the missing mass, novae and supernovae, Vulcan and transplutonian planets, and comets (a little surprisingly this, since comets are not as unusual as all that). Each chapter is written in a fair amount of detail, with the stages laid out logically by which astronomers came to their occasionally monstrous conclusions. The chapter on Eta Carinae is the most detailed in this respect, starting with its historical light curve, laying out just how Eta Carinae differs from other superficially similar kinds of stars,

discussing its infrared properties and Gratton's model of the star and concluding with its possible link with the Hubble-Sandage Variables.

The book would be enjoyed by an amateur astronomer who is ready to get to grips with some detail in astronomy. The accounts of the history of the subjects with which it deals make it a book which, say, graduate students would find it profitable to read, so that their thesis on the subjects in which they may be researching might then reference more than the last couple of years' *Astrophysical Journal*. The bibliography to each chapter gives enough references, typically to review articles of the kind that appear in *Nature*, for an easy entry into the literature dating before 1976 when the first edition of the book appeared. This, incidentally, is a translation of the second Italian edition (1979). I can pay the translation the highest compliment of all, that if it was not for a few footnotes accredited to the translators, one would scarcely notice that the book was translated.

Maffei's style is engagingly informal, although always scientific. The effects of close encounters of an astronaut with the tidal forces and event horizon of a black hole, for instance, are described with enough realism to make the image specific but not overplayed in the repellently sensational, even mystical, way which characterizes many journalistic accounts. On the contrary, this is a book which is written by an astronomer who knows the astronomical literature and has considerable skill in interpreting it at a popular level. □

Paul Murdin is an astronomer at the Royal Greenwich Observatory, Herstmonceux, UK.

The AI saga

Donald Michie

Machines Who Think. By P. McCorduck. Pp.375. (Freeman: Oxford, 1979.) £7.80.

THE task of the scientific referee is a well known contradiction. If he is himself a part of that particular action, then he cannot be impartial. If he is not, then how can he be technically competent in his task? The writing of scientific history is in similar case. It is therefore the more remarkable that Pamela McCorduck's gossipy saga on artificial intelligence, aspiring neither to impartiality nor to technical competence, has scored an undoubted overall success.

Her partiality is to the American part of the story, especially to Pittsburgh. Her saving gift is vitality, which carries her eagerly into previously unexplored catacombs of AI's pre-history. Using gold as the construction material the lame Greek god Hephaistos fashioned female attendants to help him walk. These robots not only walked, but also gave utterance from the promptings of inbuilt intelligence. A bronze android named Talos, Zeus' love-gift to Europa, patrolled the shores of Crete three times a day and hurled rocks at invaders. On catching any, he would heat himself up and fry the victim in a fiery embrace. Pandora, another female android from Hephaistos' shop, was developed under contract from Zeus to punish mankind for accepting Prometheus' gift of fire.

Joseph Golem was the artefact of the 16th century Loew, chief rabbi of Prague and friend of Johannes Kepler. The Golem's use was to spy on Gentiles. In reporting on his missions he was somewhat hampered by being mute.

Mary Shelley's tale is brought hauntingly to life, with Dr Frankenstein's creation driven half-mad with loneliness and his maker's evident physical repugnance for him. "Misery makes me a fiend!" says the 8-ft monster, and begs his master to fashion a soul-mate for him. Frankenstein, having promised this, abandons the task, with devastating effect on the creature's subsequent behaviour.

McCorduck's shrewdest move is to have gathered lengthy oral histories from numerous tape-recorded interviews for later interweaving with pre-existing records. It is startling to read Marvin Minsky's words of 1956:

The important result that would be looked for would be that the machine would tend to build up within itself an abstract model of the environment in which it is placed. If it were given a problem, it could first explore solutions within the internal abstract model of the environment and then attempt external experiments. Because of this preliminary internal study, these external experiments would appear to be rather clever, and the behaviour would have to be regarded as rather 'imaginative'.

The subsequent role of heuristically guided processes of search and inference performed on internally stored world-models has been central to AI. So too has the development of special forms of computer language in which to express what the machine knows about its world. It is therefore illuminating to read John McCarthy, saying at this same formative Dartmouth Conference that it was desirable "to attempt to construct an artificial language which a computer can be programmed to use on problems requiring conjecture and self-reference . . .".

Occasional flashes of this kind give welcome relief from the human-interest magazine style. But the latter also has its moments, not least when McCorduck permits herself to write directly from her own resources of wit and perception. On intellectual fashion:

No sooner do hemlines go down with

enormous fanfare than they go up again, the provinces growing dizzy with trying to keep pace . . . MIT thinks itself stylish, but outsiders have been known to call it faddish. Carnegie-Mellon, on the contrary, represents old-world craftsmanship, attending to detail and using the finest materials . . . But classic can be stodgy: if Queen Elizabeth of England bought artificial intelligence, she'd surely buy at Carnegie-Mellon.

For those not already members of the AI subculture, the parade of personalities, their doings and sayings, is liable to pall. Chapter after chapter is devoted to attacks by American polemicists of whom the general scientific world has never heard, aimed at targets whose names are scarcely better known, concerning philosophical issues about which few readers will excite themselves one way or the other. Yet during the same period a world-renowned British physical scientist published a concretely phrased indictment of robotics-

oriented AI activity in Britain, and this led to its almost total dismantling and dispersal. McCorduck passes over the consequential event with a brief mention: hardly excusable in a serious history.

But McCorduck's book is not offered as a serious history, any more than Aubrey's *Brief Lives* is a serious history of Oxford, or David Niven's *Bring on the Empty Horses* is a serious history of Hollywood. The reader should not come to Pamela McCorduck's whimsically titled book for instruction, or for any deep insight. But by stretching his limbs for a while in her brightly peopled landscape he can assuredly acquire, along with much enjoyment, a feel for the adventures, and the adventurers, of a scientific story at its beginning. □

Donald Michie is Professor of Machine Intelligence at the University of Edinburgh, UK.

Natural illustrations

R.D. Meikle

Nature into Art. By H. Buchanan. Pp.220. (Weidenfeld and Nicolson: London, UK, 1979.) £15.

THE title neatly indicates the scope and object of this handsome volume. It is a concise survey of natural history books with fine, coloured illustrations, for the most part published between 1700 and the middle of the succeeding century. The accompanying text is concerned not so much with the scientific importance of the publications or the scientific exactitude of the plates as with their artistic merit and technical excellence.

To deal with such a vast subject within the compass of 220 pages means, of course, that even the finest illustrators are represented by only a very few examples of their work, while many of the less distinguished must be passed by, sometimes without as much as honourable mention. Selections seldom please everyone, but few are better qualified than Handasyde Buchanan, with forty years' experience of such splendid literature, to judge what must be included, and to decide — a more invidious task — what may be omitted. His choice is well balanced, without being too detached, just as his text is concise without becoming a bare catalogue of facts. The notes on printing techniques will be particularly welcome to those who have puzzled over *del.*, *dir.*, *sculp. imp.* and *pinx.*, or who have failed to grasp the distinctions between copper and stipple engravings, mezzotints and aquatints. An appendix of book prices

Plate from Johann Leonhard Frisch's *Vorstellung der Vögel in Deutschland*, Berlin 1733-63.

current in 1934 seems, at first sight, to be a catalogue of missed opportunities, until one recalls that, in the same year, a professional naturalist, lucky enough to find work, was considered affluent on a salary of £400 p.a.

Illustrations are essential to the botanist or zoologist, indeed it may be conceded that one good plate is worth a dozen paragraphs of descriptive text, however carefully penned. But it may be questioned if more than a very few of these "grand" works were intended for scientific study. Most were destined for the libraries of those enlightened sections of the gentry who, drawn to the study of plants and animals by the lucid codifications of Linnaeus, sought, in botany and zoology, a pastime less boisterous and bloody than the chase. With few exceptions the text which accompanies such glorious illustration is a sad let-down, even that of the monumental *Flora Graeca*, too often revealing an absence of accurate data, while the *Botanical Magazine* belied its name for a hundred years by serving up what often amounted to little more than the shadow of

a commentary.

The relative immobility of plants, and their clear, definite outlines, suited the processes of engraving; indeed, in the hands of skilled engravers, the very limitations of the technique were salutary, and, with the rise of lithography, plant illustration (always excepting the work of W.H. Fitch) too often degenerated into the blurred prettiness of *The Ladies' Flower Garden*. On the other hand, lithography might almost be said to have been made for the softer world of fur and feather. Set against the splendours of Lear and Gould, many earlier illustrations of mammals (and to a lesser degree, birds) have a quaint, almost comical look, even in books like Catesby's *Natural History of Carolina*, where the plant illustrations are perfectly acceptable. Ignorance of animal movement and anatomy was, no doubt, a factor also contributing to the comparatively late development of good animal illustration: the lifeless butterflies which Ehret and his contemporaries scattered so liberally over their botanical plates are, to my mind, an unwelcome adornment, detracting from,

rather than adding to, the beauty of the flowers.

So many aspects of *Nature into Art* are pleasing that it seems almost ungrateful to end on a sour note, but I doubt if anyone will commend the extraordinary system whereby groups of legends are referred backwards or forwards to invisible page numbers, a scheme which might have been designed to ensure maximum exasperation and minimum accuracy. Less irritating, because it may have been unavoidable, is the frequent spread of animal plates across facing pages, with a hinge down the middle, breaking the poor creature's spine, and sadly detracting from the artistic effect. These are, however, small criticisms of a book which will delight all those who value a tradition (fortunately still very much alive) which reconciles, in the happiest possible way, the several objectives of art and science. □

Objectives for technology

Steven L. Del Sesto

The History and Philosophy of Technology. Edited by G. Bugliarello and D.B. Doner. Pp. 384. (University of Illinois Press: Urbana, Chicago and London, UK, 1979.) £12.25.

THIS book attempts to locate the problems of contemporary technology within the mainstream of philosophical and historical inquiry. It is the belated publication of a collection of papers first given at the International Symposium on the History and Philosophy of Technology, May 14-16, 1973, at the University of Illinois, Chicago Circle. The event was sponsored jointly by the Colleges of Engineering and Liberal Arts, attesting to the interdisciplinary character of the book and its principal subject matter. The book therefore reflects the essential beliefs of the members of the symposium: that technology plays an increasingly centralized role in our societies and our lives, and that we might study it systematically by way of the substantive and methodological approaches offered by history and philosophy.

To achieve this task, the book consists of some two dozen essays, structured around three sub-headings. The first, the history of technology, contains a number of useful papers clarifying the connections between history, society and technology. Among the papers in this section is an original piece by A.L. Donovan concerning the relationships between science and technological innovation, described by way of an

account of the close personal association between Joseph Black and James Watt in the invention of the separate condenser. There is also an insightful paper by N. Rosenberg discussing the complex interactions between technology, society, economy and values; he argues that we cannot predict the consequences of technological change without understanding the values of a society. And finally, some methodological suggestions for studying the relationships between science and technology are advanced by D.S.L. Cardwell and C.S. Smith. Smith posits that the ultimate understanding of invention and discovery depends more on the study of material objects than on the written records which historians generally use, while Cardwell argues that much of physical science as we know it was shaped by man's early industrial experiences, and not simply the other way around as many people believe.

The papers in the second section are grouped under the heading, the philosophy of technology. D. Wojick, for example, shows the utility of a Kuhnian model of scientific change to describe what he calls "technological revolutions" (nuclear power, food additives, and water resources management in the United States are his examples); while M. Bunge gets down to the serious job of characterizing the relationships between technology and the various branches of philosophy: epistemology, metaphysics, axiology, ethics and legal philosophy. In addition, there are papers concerning the relation between modern technology and political theory, as well as essays which trace the history of the philosophy of technology to its early origins. Many papers in this

section contribute detailed bibliographical materials that will be quite useful to specialists and philosophers, but are probably less interesting to the general reader.

The book concludes with a section on the future of technology which I found too brief and largely disappointing, perhaps because of the many new developments since the symposium was first held more than six years ago. I would like to have seen the important relationships between technology and social change explored more directly, and there could have been additional material regarding the anticipated affects of contemporary technological enterprises such as electronic message transfer, new biological techniques, computers, and so on. Furthermore, little attention was afforded either to the important issue of technology assessment, or to the areas of alternative technology and technology transfer. What we get are eloquently written but largely familiar statements like "technology subverts human values and impinges upon individual freedom", "we must understand technology to help provide for the continued existence of the human race", and the like. No-one denies the importance of such issues, but serious scholars of technology are apt to find the section on the future of technology less useful than the preceding ones; it is at best incomplete.

Beyond the content and organization of the individual essays, the book as a whole stresses at least two general themes, which seem to have been the central messages of the symposium. First, it is clear that the phenomenon of technology deserves continued, if not more systematic, study by scholars. Comprehensive studies and

New books from CAMBRIDGE

Flora Europaea

Volume 5: Alismataceae to Orchidaceae

**Edited by T. G. TUTIN, V. H. HEYWOOD,
N. A. BURGESS, D. M. MOORE, D. H. VALENTINE,
S. M. WALTERS and D. A. WEBB**

Flora Europaea presents, for the first time, a synthesis of all the national and regional floras of Europe. It is based on a critical review of the existing literature and on studies in herbaria and in the field. It aims to be simple as well as authoritative, and should enable the reader to name as far as its sub-species any fern, conifer or flowering plant growing wild or widely cultivated. This, the fifth and final volume, covers the Monocotyledons.

'*Flora Europaea* is a triumph of international organisation and co-operation as well as a work of exceptionally high value and importance.'

The Pre-Glacial Pleistocene of the Norfolk and Suffolk Coasts

R. G. WEST

This account provides the basis for reconstructing environmental history in the immediate pre-glacial period of time. A number of climatic stages have been recognised, defined and related to the history of sedimentation, vegetation and sea-level change. The work is composed of entirely new material and is likely to become a classic in the field. It will be welcomed by geologists, botanists, archaeologists, zoologists and geographers. £40.00 net

Gases, Liquids and Solids

Second Edition

DAVID TABOR

Professor Tabor shows how many of the bulk properties of the three common states of matter can be explained in terms of intermolecular forces and thermal energy. The second edition includes an extended discussion of van der Waals forces and a section on the stability of colloids. This book will be ideal for undergraduates in physics and chemistry at universities and polytechnics and for sixth-form scholarship candidates in science.

Fundamental Tissue Geometry for Biologists

K. J. DORMER

The quantitative description of tissue geometry is of fundamental biological importance, and this is the first coherent account of the subject. Mathematical modelling techniques are used to link the fate of individual cells to the general processes of growth and differentiation, and the geometrical aspects of these processes are successfully reduced to calculation. The book will be important as a practical aid to routine computation for students and research workers in histology, developmental biology and tissue culture. £15.00 net

Genetic Models of Sexual Selection

PETER O'DONALD

This book shows how sexual selection occurs in populations of animals and gives rise to the evolution of particular characteristics. Some females prefer to mate with males possessing such characteristics. The author constructs general models giving probabilities that these males are chosen as mates, and in many cases the rarer type of male gains an overall advantage. The models are then analysed in genetical terms and their evolutionary consequences deduced. This book will be of interest to evolutionary, ecological and population geneticists and their students.

Human Ethology

Claims and Limits of a New Discipline

**Edited by M. von CRANACH, K. FOPPA,
W. LEPENIES and D. PLOOG**

Ethology has proved a very successful approach to the study of animal behaviour, emphasising its biological basis and evolutionary origins. A natural development has been to apply ethological principles to the behaviour of *man*, which has proved highly controversial. In this book, distinguished ethologists and specialists in other disciplines draw on their research experience to test whether *human* ethology may justifiably be considered a legitimate new discipline.

The Uranium People

Leona Marshall Libby

The story of the Manhattan project told by one who was there – the youngest and only woman member of the scientific team that built the first nuclear reactor. While recalling the scientific background and progress of the development of nuclear weapons, Leona Marshall Libby is mainly concerned with the diverse group of very talented personalities with whom she worked. These included such central characters as Nobel Laureate Enrico Fermi, Edward Teller, Leo Szilard, Herbert Anderson, Robert Oppenheimer and many other talented individuals who played such an important role in scientific history. The author describes their scientific approaches and personal lifestyles, and tells of the teamwork and the conflicts as they worked together to create weapons of mass destruction.

programmes concerned with technology/society relationships should receive continued support. But the essential task, as M. Kranzberg notes in his introductory essay, is not simply study and reflection, but to embark on the difficult job of developing more precise conceptual, theoretical and methodological frameworks that allow the codification of diverse results from many fields of inquiry. Specifically, I would add that we need to work on higher level theories of social and technological change which can better explain how we got where we are, and where we might be headed in the future. This means, among other things, reaching basic conceptual agreement on key terms often used loosely and broadly — terms like “rationality”, “automation”, “efficiency”, “social change”, “science”, and the very concept of “technology” itself. Many of the essays in the book outline ways we may begin to tackle these important tasks.

Second, and I believe quite correctly, several papers put forth the theme that society must develop better moral and ethical perspectives on the control and improvement of technology, and that scholars of technology have a key role in the effort to produce better and more humane technologies in the years ahead. The job cannot be done simply by politicians, technocrats and administrators, but must be informed by the arts, humanities and the social and natural sciences as well. The task is truly interdisciplinary in character; and greater levels of improvement will not emerge without broadly based action which ranges far beyond the efforts of historians and philosophers working alone.

In sum, this compilation of essays will be useful to specialists as well as to general readers wishing to grasp the broad contours of the study of technology. It is well documented and mostly clearly written, although the lack of a subject index is annoying and hampers its value as a research tool; this, I believe, should be a major function of such a book. Nevertheless, I think anyone seeking an understanding of the full range of perspectives on technology and society will find time invested here worthwhile. The book's essays illustrate well how technology affects, both positively and adversely, social and political institutions, and how the human psyche — those ways in which we think, act, and relate to each other and the world — are influenced in directions that we are only beginning to foresee. It is to be hoped that such historical and philosophical materials can inform policy objectives, and help us decide on future technological choices as individuals and societies. □

Steven L. Del Sesto is Assistant Professor in the Program on Science, Technology and Society at Cornell University, Ithaca, New York.

Understanding non-crystalline materials

D.C. Licciardello

Electronic Processes in Non-crystalline Materials. Second edition. By N.F. Mott and E.A. Davis. Pp.590. (Clarendon/Oxford University Press: Oxford, 1979.) £29.

THE second edition of this enormously successful book is faithful to the Mott and Davis style. The authors expand on their laudable attempt at unifying the vastly growing experimental literature in this field within the framework of some very general theoretical concepts. The book represents the single work which provides a focus to a field which, before Mott and Davis, had a divergent breadth.

The task is particularly monumental for at least two reasons. Firstly, the theoretical foundation on which the treatise is based is not well established. Indeed, the current literature is rife with new calculations which are at variance with some of the more fundamental ideas on which the exposition depends heavily, such as the minimum metallic conductivity. Secondly, the experiments being reported give results which still vary, to some extent, from laboratory to laboratory. This is partly due to the substandard quality of early experimental work, since only recently has enough attention been brought to the subject (largely through this book) to attract the interest of the world's best solid state physicists. Mostly, however, non-crystalline materials add a new dimension to the experimenter's problem in that materials must be characterized by method of preparation in addition to chemical makeup, e.g. one does not describe the generic properties of amorphous silicon.

The book describes the basic theory in the first four chapters. Care is taken, in traditional solid state format, to separate the non-interacting problem (Chapters 1–3) from the interacting one (Chapter 4). The basic theoretical problem, in the first case, concerns the behaviour of an electron in a random potential. The theory was first illuminated by P.W. Anderson in 1958, and Mott and Davis consider the Anderson mechanism for electron localization fundamental to the understanding of the properties of non-crystalline systems. The theory is discussed in some detail within the context of application to real systems. Thus, the exposition is much less formal than the original Anderson treatise and attempts are made to recast the concepts within a descriptive band theory. Herein lies the real value of this work for the solid state experimentalist.

The important problem of conduction in random media is discussed at length. The book demonstrates within fairly simple

analysis the absence of conductivity for Anderson localized electrons. The transition to conducting behaviour when the randomness is reduced or the electron density is increased is treated and Mott's notion of the minimum metallic conductivity is described.

The effect of correlation on transport and localization (Mott transition) persists and is expanded upon in the second edition. The term Fermi glass is used to denote a system of localized electrons in which localization may be due to randomness (Anderson) or electronic correlation (Mott). Mott and Davis discuss, as a class, those systems which undergo transitions from the Fermi glass state to metallic behaviour. To be sure, the two phenomena are distinguished, although the extent to which they are fundamentally different is again a current theoretical research topic. The discussion (Chapter 4) on metal-insulator transitions is unusual for the text in that the canonical examples of these effects are crystalline. Thus, Mott and Davis discuss doped semiconductors and narrow band transition metals.

The book, however, is mainly concerned with amorphous semiconductors. These are divided somewhat arbitrarily according to the local valence requirements of their constituents, Selenium and tellurium, however, are treated separately from the compound chalcogenide glasses. Mott and Davis make an invaluable contribution by extracting the most relevant details of the vast literature on these materials and by describing the basic electronic measurements in comparison. This kind of contribution defines the field and makes it particularly amenable to the newcomer.

Any treatise which ventures into a synthesis of a rapidly advancing subject runs the risk of being dated fairly quickly. The problem is even more serious when the authors engage, as is done here, in an explication of many measurements in terms of a general theoretical framework which, as pointed out above, is still controversial. For example, it is fair to say that at this writing, current renormalization group calculations give a conductivity at the Anderson transition with no minimum value. Much is made, in the second edition, of experiments on conduction in an inversion layer at the semiconductor/glass interface. The authors use this to support the notion of a universal minimum metallic conductivity in two dimensions. Again, there are recent calculations which suggest the absence of diffusion altogether in two dimensions. More recent experiments (not included in the book) tend to support this, although the mechanism for localization is still unclear.

The basic model presented for understanding non-crystalline semiconductors is a picture of an ideal structure into which the authors imbed a certain concentration of “defects”. The concept of a defect

within a random structure is difficult to define; however, the idea is that the electronic properties of the ideal structure would be similar to that of the corresponding crystal (if one exists). Thus, the defect, in this sense, is important in determining the specific electronic properties of the amorphous semiconductor. This is a rather extreme point of view for the structure of glass, in my opinion, yet the authors are able to cast much of the data within this framework. It is fair to point out, however, that models do exist which minimize the effect of local

structural inhomogeneities but do enjoy similar success in explaining much of the data. These theories invoke a strong lattice interaction and, indeed, Mott and Davis discuss the simple negative-U model first introduced by Anderson but narrowly interpreted here. Thus, the basic electronic structure for glassy semiconductors is not universally agreed.

The reviewer with the broad view may dismiss much of the current controversy as detail and indeed it is somewhat inconsequential when the contribution is taken as a whole. It is certainly true that some of the

analysis given in this book will be finally shown to be incorrect. This is the risk the authors boldly took in attempting to characterize and define a new branch of solid state physics. It is fitting that the Nobel Prize in physics was awarded to Sir Nevill Mott for contributions to this field, many of which are included in this book. □

D.C. Licciardello is an Assistant Professor of Physics at Princeton University, Princeton, New Jersey.

Heavy stone circles

R.J.C. Atkinson

Rings of Stone: The Prehistoric Stone Circles of Britain and Ireland. By Aubrey Burl, with photographs by Edward Piper. Pp.280. (Frances Lincoln/Weidenfeld and Nicolson: London, UK, 1979.) £9.95.

AUBREY BURL'S position as the leading authority on stone circles was established by the publication of his *Stone Circles of the British Isles* (Yale University Press, 1976), a work for scholars which is not likely to be superseded within the present century. *Rings of Stone* is a companion volume for the layman, extensively and admirably illustrated, but unencumbered by the *apparatus criticus* of scholarship. There is a glossary, a reading-list confined to books and monographs, and an index. The reader who is stimulated to seek primary sources must consult the bibliography and gazetteer of his earlier book.

Apart from its weight (1.2 kg) and its 27 colour plates on art paper, which are at the mercy of the fine soft rain which falls so

frequently on stone circles, this is an excellent vade-mecum for the holiday traveller with a purpose, whether it be specifically archaeological or aesthetic. The amateur prehistorian will find it useful in guiding him to the best-preserved and most easily visited sites. The traveller bent, in the Romantic tradition, upon viewing these rugged and enigmatic works of man against their landscape background will be well served also, provided that he remembers that the rocky and treeless terrains which now surround many stone circles are themselves the product of man (and indeed of the builders of the circles themselves), and not of nature alone.

Readers with either purpose will be guided in their travels by the latter two-thirds of this book, which describes and illustrates fifty stone circles in Britain and Ireland which are well preserved and easily visited. For each region there is a map showing the sites and the main roads. For each site there is a map reference and a plan and photographs, as well as a textual description which will delight the reader by its aptness and sensitivity, either from his prior knowledge of the monument or after his first visit. It is a pity, however, that there are no figured scales for the plans, which vary widely in their ratio of

reproduction; but the principal dimensions are given in the headings.

The photographs, of which there are 106 in black-and-white as well as those in colour, are mainly the work of Edward Piper, who has inherited much of the genius of his father, the artist John Piper. Apart from one or two of the colour plates, in which the printers have achieved an overall hue which is displeasingly chlorotic, this is the finest set of pictures of prehistoric antiquities which has ever been assembled between one pair of covers. It is a picture-book in its own right, quite apart from the accompanying text, and it will stimulate the reader to see more of these sites than the photographs can show. For those who are unable, or unwilling, to venture far from the slippers comfort of their own firesides, the combination of visual and verbal description conveys very well the variety of size and character of stone circles, and readily explains their appeal to the antiquaries and topographers of the Romantic Age, which is still happily not dead.

This guide for the visitor is preceded by ten short chapters, in which Burl summarizes his unrivalled knowledge of the stone circles of the British Isles and gives his own views about their purpose and date. He begins with one of the principal regional groups, which is also morphologically and archaeologically the most coherent: the Recumbent Stone Circles of north-eastern Scotland. Here ten or eleven stones, rising in height towards a pair flanking a recumbent slab lying on edge and often with a top surface accurately horizontal, surround a low annular cairn of small boulders with a small central open space, in which excavation has frequently revealed signs of burning and small deposits of cremated human bone, accompanied significantly often by fragments of quartz.

The paucity of the human remains leads Burl to conclude, and doubtless rightly, that these were not cemeteries, but places of worship for a single extended family, sanctified at their inception by a token burial or burials, perhaps as the sequel to deliberate sacrifice. He notes, however, that although a single family could have

Edward Piper.

raised all the upright stones, the transport of the recumbent stone (typically of 20 tonnes or more) required the combined efforts of the able-bodied members (and perhaps the males only) of a number of families. This provides a tantalizing glimpse of community action, and perhaps of a clan organization, in the late third and early second millennium BC; but its details are beyond the limits of valid inference from the evidence.

Burl also shows, in more detail than in his earlier book, that the position of almost all the recumbent stones lies within the azimuth range of the moon at its minimum declination; and he therefore posits a symbolic link between the moon and the dead who sanctified these sites.

In the remaining hundreds of stone circles elsewhere there is little to be seen of any recurrent pattern, save that they are of stone and approximately circular. Some but not all of the few which have been comprehensively excavated have produced burials, but again of a token or dedicatory kind, or as manifestly later additions, in the Early Bronze Age, to monuments built centuries before. They vary greatly in size,

from the huge ring at Avebury to tiny circles which would very nearly fit into the study in which I write this review; and in date they seem to cover a period of about two thousand years, starting around 3,500 BC. Within such wide ranges it is probably futile, as Burl implicitly recognizes, to seek any simple or universal explanation. It is better to admit, however reluctantly, that there are many interesting questions about the prehistoric past which are *per se* unanswerable, simply because there are no documents to give a clue to motives. Motive, except in the trivial sense of intending to do what was done, cannot be inferred from inanimate objects and structures. In answer to the question 'Why?' the evidence is dumb.

This otherwise excellent book dismisses too forthrightly the putative evidence from stone circles for the early development of scientific concepts. For Burl, the megalithic yard is "a chimaera, a grotesque statistical misconception". It is indeed a product of statistical inference; but two independent treatments of the data by different means have agreed, at the least, that further investigation is necessary

(*Trans. R. Soc. Lond. A276*, 1974; *J. R. Stat. Soc. A139*, 1976).

Burl likewise implicitly rejects Thom's hypotheses about how the non-circular rings (flattened circles, eggs, compound rings) were set out, on the grounds that alternative constructions, using only pegs and a loop of measuring cord, yield an equally good fit to the stones surveyed. He may be right; but he ignores or evades the point that even if these shapes, manifestly deliberate and not accidental, are no more than the fossilized remains of games with pegs and string, they none the less constitute the foundations, gropingly laid maybe, of pure mathematics.

The astronomical aspects of stone circles can be assessed only statistically, using the largest samples available, because putatively significant alignments can obviously occur by chance. Independent checks of the claims of Thom and his followers are only now in progress. Their outcome should not be prematurely judged, in advance of publication. □

Electronic theory of cancer

M. M. Coombs

Submolecular Biology and Cancer. Ciba Foundation Symposium, No. 67. Pp. 349. (Excerpta Medica: Amsterdam, 1979.) \$42.50, Dfl. 87.

THIS book reports the proceedings of the 67th Ciba Foundation symposium, held in honour of Albert Szent-Györgyi on the occasion of his 85th birthday in 1978.

In an introduction by the Chairman (R. J. P. Williams) it is noted that although "submolecular" refers to systems at a lower level than whole molecules, in the present context it is largely confined to electrons. Szent-Györgyi next outlines his views on "the living state and cancer", and the possible relationships between submolecular biology and cancer are enumerated. The greater part of the book is devoted to fifteen lectures, each with its own discussion, and ends with a general consideration of Szent-Györgyi's hypothesis.

The sharp distinction between living and inanimate matter leads Szent-Györgyi to conclude that a specific physical state underlies life. The subtle reactivity of living systems is thought of as an inherent property of the constituent proteins, brought about by removal of single electrons from their otherwise fully occupied orbitals. Positive electron holes

thus produced lead to electrical conductivity, with the ability of the desaturated proteins to carry information in the form of electrical signals. It is proposed that "the living state is the electronically desaturated state of molecules, and the degree of development and differentiation is a function of the degree of electronic desaturation". When life began on Earth the atmosphere lacked molecular oxygen; electronic desaturation of proteins was accomplished by simple aldehydes, such as methylglyoxal ($\text{CH}_3\text{CO}\cdot\text{CHO}$), which are good electron acceptors. This led to a low degree of development, termed the α -state. Later the advent of atmospheric oxygen, a much better electron acceptor, led to the highly developed β -state existing today. Here a related molecule, ascorbic acid (vitamin C), acts essentially as a catalyst for the electronic desaturation of proteins by oxygen. Cancer is thought of as a reversion to the α -state.

It is obvious from the studies described in the subsequent chapters that little evidence can be found for electrical conductivity in proteins treated with electron acceptors, although here the virtual impossibility of making measurements on proteins in their native state may obscure true results. Nor is the anti-cancer activity of certain aldehydes apparently mediated in the way suggested by the hypothesis; moreover, it now seems very doubtful whether vitamin C is useful in the clinical treatment of the disease. Furthermore, experiment does not support the idea that there are differences in free radical levels between normal and tumour

Albert Szent-Györgyi.

Courtesy of Owen & Moroney, London.

cells. However, R. Damadian, in developing the technique of whole-body nuclear magnetic resonance scanning, can distinguish normal from cancer tissue by the prolonged relaxation of protons in the latter. This indicates increased disorder in the structure of water in tumours, but just how this ties in with Szent-Györgyi's theory is unclear. To summarize, it is disappointing that this novel hypothesis has so far failed to find solid experimental confirmation.

The book is well produced and free from errors; its cost does not seem unreasonable in this age of unreasonable prices. □

Fludd's philosophy

P. M. Rattansi

Robert Fludd and His Philosophicall Key. Introduction by Allen G. Debus. Pp.156. (Neale Watson: New York, 1979.) \$40, £20.

IN 1620 Francis Bacon published his *Novum Organum*, with a dedication to James I, urging him to support his enterprise, "that so at length, after the lapse of so many ages, philosophy and the sciences may no longer float in air, but rest on the solid foundation of experience of every kind . . .". At about the same time, the physician Robert Fludd had completed a *Philosophicall Key* "to unlock and open the meanings of that Macrocosmicall and Microcosmicall Philosophy". He, too, dedicated it to James I, hoping the King's patronage would shield him "from the Harpys talents and envious endeavours of this World".

Fludd agreed with Bacon that Aristotelian science was to be replaced by one based on "ocular demonstration" and dedicated to the relief of human misery. Like him, he praised atomism, but was more inclined to explain nature's operations in terms of a 'spirit' active in all things. But Fludd believed in a 'Christian' philosophy of nature, the principles of which would be drawn from the account of creation in the text of Genesis. Bacon condemned the "unwholesome mixture of things human and divine" since it gave rise to "not only a fantastic philosophy but also an heretical religion". Fludd associated the greatest secret in nature, the principle of life, with light and the breath of the Lord, while Bacon denounced such notions as "superstitious".

His major works had already appeared in Latin, and had involved Fludd in controversies with Kepler, Mersenne and Gassendi. The *Key* was written in English to silence critics at home. Fludd thought his "experimental demonstrations" would convince readers of the truth of his ideas. Relying on an analogy between the Sun in the Universe, the heart in the human body, gold in the metalline and wheat in the vegetable kingdoms, Fludd chose to concentrate on experiments on wheat. After all, had it not been compared to the Second Person of the Trinity, and was it not Christ's referring to bread as his body which had set the Christian world "in combustion"?

The planting of the seed in the ground and the generation of wheat had exemplified the pattern of death and resurrection to the Christian alchemist. Fludd pointed out that as the plant grew, the quintessence in it rose to the stalk and was concentrated in the wheat grain. By a sympathetic magnetism, the most spiritual part of the plant would then draw down

more and more of the aerial spirit. This process could be emulated by the chemist, and Fludd believed he had succeeded in obtaining the universal spirit in the form of a "white crystalline" substance.

Fludd's claims may seem extravagant to us, his reasoning contorted and his "ocular demonstrations" quite unconvincing. It is disconcerting, therefore, to recognize in his work themes which recent historical research has unearthed in the alchemical studies which occupied a great deal of Isaac Newton's most creative period: the true interpretation of the alchemical foundation text, the 'Emerald Tablet'; the 'magnet' to draw down the aerial quintessence; and the involvement of light in generation in the three kingdoms of

nature. He represents a style of thought which cannot be neglected if we are fully to comprehend those whom we recognize as the pioneers of modern science.

The *Key* has been published for the first time from the manuscript at Trinity College, Cambridge, with an Introduction by Allen G. Debus. The text itself occupies 93 pages and has been supplemented with an extensive account of the life and work of Fludd. The work, written in a rhapsodic style which occasionally breaks into verse, makes Fludd's ideas a little more accessible to the modern reader. □

Recombination in phage and fungi

H.L.K. Whitehouse

Genetic Recombination: Thinking about it in Phage and Fungi. By F. W. Stahl. Pp.333. (Freeman: San Francisco and Oxford, 1979.) £12.90.

THE publication of a book on genetic recombination by one of the leading workers in the field is an important event for geneticists. Recombination was discovered in the early years of this century and became a central issue in genetics with the realization that exchange of segments between homologous chromosomes was involved, in addition to the random orientation of the paternal and maternal members of each chromosome pair on the spindle at the first meiotic division. Recombination took on a new dimension about 30 years ago with the discovery of its occurrence in prokaryotes, and with the recognition that both in prokaryotes and eukaryotes understanding the process of exchange was likely to require detailed knowledge of the biochemistry of DNA. Since that time it has been essential, if a general view of the subject was to be obtained, that results derived from prokaryotes and eukaryotes should be integrated. To achieve such integration is difficult, as the life-cycles, and therefore the experimental techniques and kind of information obtained, are so different: the prokaryote- and the eukaryote-worker speak such different languages that they may barely understand one another. It is greatly to Stahl's credit that he has attempted in this book to bring about a synthesis of results from bacteriophages and from fungi, as these are the organisms that have contributed most from each kingdom. The phages discussed are lambda and T4 of *Escherichia coli*.

The first two chapters give the basic information about the exchange process obtained from progeny chosen on a random basis, in fungi and phages, respectively; and the next two chapters give the fuller picture when both products of an exchange are recovered — that is, tetrad analysis and single burst analysis. The implications of the duplex structure of DNA are introduced in Chapter 5. Then follows an important chapter on the surprising results that have been obtained, both in phages and fungi, from investigations with very closely linked mutants. Together with an appendix giving the algebraic basis of the concepts introduced, this chapter constitutes one quarter of the entire book. The following two are concerned with conversion and its association with crossing-over; and, after a consideration of recombination chemistry, the book concludes with lengthy discussions of current hypotheses. There is no account of transposons or phage Mu.

The lay-out of the chapters, although logical, does not necessarily make the subject matter easy to comprehend, and certainly leads to considerable repetition. Thus, having learnt in the first chapter that crossing-over takes place between homologous chromosomes, one has in a later chapter to replace this with the notion that the exchanges occur between daughter chromatids rather than whole chromosomes. Again, in discussing aberrant asci, one of the five basic kinds is treated in a different chapter from the others, because it does not have unequal numbers of the two parental genotypes and therefore does not qualify for consideration in a chapter on conversion. Yet all the types of aberrant segregation are associated with crossing-over and it is arguable that the simplest approach is to treat them all together.

Some of the difficulty for students in understanding what is known about genetic recombination derives from complexities inseparable from the organisms investigated. Thus, in lambda not only are there two recombination

NEW SPRING TITLES

BIOLOGICAL SCIENCES

THE SCIENCE OF GENETICS 4th Edition

George W. Burns — (Ohio Wesleyan University)

The fourth edition of this introductory text in genetics begins with 'Classical' genetics and progresses through molecular Genetics using the experiments of scientists, set within a chronological framework to give the text a problem oriented discovery approach. New to this edition is an increased emphasis on human genetic patterns with expanded treatment of sex anomalies, chromosome aberrations, and genetic polymorphism of humans. Expanded and added material includes: Information on the normal and abnormal human Karyotype; list of selected chromosome assignments for the genetic loci of mankind; treatment of multiple histocompatibility complex and its human leukocyte antigens (HLA); and nucleoprotein untrastructure.

AGRICULTURE

MODERN BREEDS OF LIVESTOCK 4th Edition

Hilton M. Briggs — (South Dakota State University)

Dinus M. Briggs — (University of Arkansas, Fayetteville)

This book presents a history of breeds of livestock and breed types. It provides the latest information about all breeds currently found in the United States, emphasizing their strengths and weaknesses and placing special emphasis on the contributions a breed has made and will probably continue to make in the future. This latter focus will be of special interest to students of agriculture who are looking at new breeds to influence European livestock.

736pp 02.314730.X hb. May 1980 £14.95

THE MARKETING OF AGRICULTURAL PRODUCTS 5th Edition

Richard L. Kohls —

Joseph N. Uhl — (both, Purdue University)

Little or no background in economics is necessary for students to study food marketing with this established text. New to this edition is additional material on the interrelation of food markets; the International Market for Food; the price structure, and market development and the futures market.

576pp 02.365640.9 hb. May 1980 £12.25

CROP PRODUCTION: Principles and Practices 4th Edition

Darrel S. Metcalf — (University of Arizona)

Carbondale)

This initial course text provides the information necessary to formulate the basic principles of crop production. Organized on systems basis with sections on grain production, forage and pasture production systems etc. this edition contains new chapters on the world food population problem; climate and crop production and pollution while other material has been expanded.

672pp 02.380710.5 hb. July 1980 £12.25

TEN-STATEMENT SPIRAL BASIC: From Calculator to Computer

Richard E. Mayer — (University of California at Santa Barbara)

Here is a concise, easy-to-use introduction to computer programming. It presents the core set of BASIC language statements and features so that the reader will be able to write programs in BASIC. It does not however, overwhelm the reader with complicated details and programs that might lead to frustration. The calculator — an input-output device familiar to everyone — is used to illustrate more complex computer programming, and underlying concepts such as memory, logic, input-output and control functions are made explicit, before being used as the foundation for the more complex concepts.

Circle No. 27 on Reader Enquiry Card.

systems specific to it, but the host recombination pathways also act on the phage. Furthermore, the method by which lambda packages its DNA in the head of the virus probably leads to a bias in the recombination events shown by the progeny. With T4 the complexity of the experimental results arises from the extraordinary genetic system that prevails in this phage, which has linear genomes that are circularly permuted with respect to one another. Although a concise account is given of the relevant results, it would be an advantage to students if they already had some knowledge of recombination studies with *E. coli* and these phages.

The book is addressed to graduate students and final-year undergraduates, but I fear that many will find it difficult reading. The problems at the end of each chapter will no doubt help towards a better understanding, though some of these will certainly present a severe challenge for students. Fortunately, the solutions are given later in the book. The clarity of thought that the book constantly demands is helped by a profusion of unnumbered small diagrams which form an integral part of the text. In some of the diagrams the differences in line thickness that indicate the parentage are easily overlooked, and there are no legends to draw one's attention to them. The author's entertaining, often colloquial, style helps to enliven the book.

Errors are few, but Figures 8-1 and 8-2 have been transposed and an incorrect reference is given in this chapter for data on

Sordaria asci with 5:3 ratios for spore colour. In the previous chapter Rossignol and Haedens' work is discussed without reference to them. There is a useful glossary but Stahl's new term, 'splatch', is not included though freely used in the text. It is surprising in a book on genetic recombination to find no reference to the important contributions to the subject by Benbow *et al.*, Ephrussi-Taylor *et al.*, Spatz and Trautner or Tiraby *et al.*, even though their work relates to organisms other than those with which the book is primarily concerned.

My chief criticism of Stahl's book is that it does not give a balanced view of the current state of knowledge of recombination in eukaryotes. Hypotheses involving fixed pairing segments, such as his so-called "sex-circle" model, are discussed without drawing adequate attention to the conflict they present with a considerable body of data. He lists eleven features of the recombination data for *Saccharomyces cerevisiae* and implies that these results are so different from those found with other fungi as to demand a quite different explanation. But most of the results with yeast have also been found in other fungi; and to me the similarities are much more impressive than the differences. He supports the idea of break-and-copy by reference to work on phage $\phi 1$ without acknowledging that the authors subsequently abandoned this hypothesis for a more conventional one depending on heteroduplex DNA. And why suppose that

in fungi two crossovers (reciprocal exchanges) may occur in very close proximity in the same two chromatids when there is no evidence for this? Stahl repeatedly raises the subject of interference between crossovers, even to the final sentence of the text, where he says "... we would all feel better if a good molecular explanation for the facts of interference were neatly wedded to some of those models", referring to those he has been discussing. But he seems to overlook the very great distances, in molecular terms, over which interference often acts, and the lack of it across the centromere. It seems likely that interference is a phenomenon superimposed on the basic crossover mechanism rather than a primary feature of it. When discussing Holliday's recombination model in Chapter 8, Stahl argues that interference should lead to an excess of recombinant over parental flanking marker genotypes in association with conversion, but Holliday himself (*Phil. Trans. R. Soc. B277*, 367; 1977) draws the opposite conclusion.

Despite these criticisms, Dr Stahl is to be congratulated for producing such a challenging and thought-provoking, if controversial, work. It should draw attention to the many unsolved problems in this field and provide a stimulus for further research. □

H.L.K. Whitehouse is Reader in Genetic Recombination in the Department of Botany, University of Cambridge, UK.

Illustrated black holes

R.L. Znajek

Black Holes. By W. Sullivan. Pp.303. (Anchor Press/Doubleday: Garden City, New York, 1979.) \$17.95.

SULLIVAN'S *Black Holes* begins with a bang. Literally. The first chapter is about the Tunguska event — the great Siberian explosion of 1908. This is tenuously linked to the title by a theory that the explosion was caused by a small black hole falling through the atmosphere (Jackson and Ryan, *Nature* 245, 88-89; 1973). Like all good theories it made a prediction: the hole passed through the Earth and emerged over the North Atlantic Ocean, causing a similar explosion as it left. This should have caused atmospheric vibrations comparable to those detected from the original event. It turned out that no such vibrations were detected from the North Atlantic (Beasley and Tinsley, *Nature* 250, 555-556; 1974), and so the theory now seems untenable. There is of course no shortage of other ideas, ranging from the exotic (an

exploding nuclear-powered spacecraft) to the quite plausible (a small comet or meteorite). Sullivan tells us about all of them, and this gets him into digressions about anti-matter and carbon-14 dating. We are treated to maps, eyewitness reports and even photographs of a man who was blown off his porch by the blast. It is mostly quite interesting. Like the rest of the book, it has little to do with black holes. But the title presumably sells.

Black Holes is in fact an account of some of the more dramatic goings-on in modern astronomy. It deals with white dwarfs, pulsars, X-ray sources, quasars and cosmology, as well as with things that might have exploded over central Siberia. Sullivan, being Science Editor of the *New York Times*, writes in an appropriately journalistic 'who-did-what' manner. He emphasizes observations and is short on theory. The trouble is that black holes are inherently theoretical objects. They cannot, by definition, be seen or photographed. Events happening near a black hole can be observed, and the hole's presence deduced theoretically. A book about black holes should certainly explain why many astronomers think they exist, and this one does. It should also make a serious attempt to explain what they are,

and this means more than just stating that gravity becomes so strong that not even light can escape.

I am not asking for a layman's guide to tensor calculus and the Einstein equations. I am suggesting that one can give a precise but non-mathematical account of relevant aspects of special and general relativity, such as light cones and frames of reference. By showing how light cones are tilted at the surface of a black hole, one can demonstrate why the surface is an 'event horizon' and why leaving it is precisely equivalent to travelling faster than light. (A spaceship that can travel faster than light can get out of a black hole. Scientists depicted in the recent film *The Black Hole* seem surprisingly ignorant of this fact.) Laymen may not understand mathematics, but most of them can read maps, and so any popular account of black holes should include plenty of space-time diagrams, which are just maps showing the location of events in space and time. The best example of what I have in mind is Kaufmann's book *The Cosmic Frontiers of General Relativity* (Little, Brown: Boston, 1977), which might almost be accused of being over-illustrated. Sullivan's book is crammed with photographs of astronomers, telescopes, rockets and galaxies, but I cannot

find a single space-time diagram in it.

Having made my complaints, I must confess I quite liked the book. All that is wrong with it is the market it is aimed at. It is basically an anecdotal history, and as such is more likely to interest astronomers than the general public. It provides a personal dimension which is normally absent in original papers and review articles. Sullivan records the comments of scientists in the process of discovering, debating or just feeling confused. The result is somewhat chaotic, but that is what

science is often like. Sullivan himself describes his book as "an ongoing scientific mystery story". He provides an excellent set of "Selected References", the main merit of which is that they are not selected. Most of them are very inappropriate for laymen, but they are precisely what is required by astronomers wishing to get to the science behind the anecdotes. The book would be improved by the removal of some of the weaker attempts at popularization, such as the summing-up of diffraction as "light plus

light equals darkness". There are a few inaccuracies, like the statement that in an accretion disk "gas would spiral in more rapidly were it not for friction". (Gas would not spiral in at all were it not for friction.) I can nevertheless recommend this book for the history section of any astronomical library. I would recommend Kaufmann's book to any layman who wants to know about black holes. □

R.L. Znajek is a King's College Research Fellow at the Institute of Astronomy, Cambridge, UK.

Thames revival

R.J. Wootton

The Tidal Thames. By Alwyne Wheeler. Pp.228. (Routledge and Kegan Paul: London and Boston, 1979.) £8.95.

THE tidal Thames runs from Teddington Lock, west of London, eastwards to the North Sea. Bisecting the capital city, this length of the river has streamed through British history, providing a means of transport for men and their commerce. Until the nineteenth century, it also supported flourishing fisheries which supplied London with such esteemed food fish as salmon, smelts, eels and whitebait. But thereafter a combination of events destroyed these fisheries and left a long stretch of the tidal river apparently lifeless. Only in the past two decades has this degradation of the river been reversed, and now fish can once again be found throughout the tidal Thames. Alwyne Wheeler, an ichthyologist at the British Museum (Natural History), has played an important role in recording the return of fish to the Thames. His book tells of the death and revival of the river as a habitat fit for fishes.

In the first half of the book, Wheeler describes the decline in quality of the river and its effects on the fisheries. Industrialization and population growth were the major factors. Pound locks were constructed to improve navigation on the river, but these hindered the movements of migratory fish and made their capture easier. Gas works and other industries poured their toxic by-products into the river. The primitive methods for the disposal of human excrement, cess pits with the night soil spread on agricultural land, became inadequate so that disposal

through sewers was introduced, a development encouraged by recurrent outbreaks of cholera. At first the sewers discharged directly into the river in London, but this led to such gross pollution that on an infamous occasion in 1858, "the year of the great stink", committee meetings in the Houses of Parliament were suspended because of the stench. A great Victorian engineering scheme was initiated, and in a few years 84 miles of sewers had been built which carried London's wastes eastwards to empty into the river downstream of central London. Sadly, the site for the outfalls was miscalculated, and the sewage was trapped in the water mass by tidal movements. This area of the river, receiving most of London's excrement, became so polluted it was claimed that suicides died of poisoning before they could drown themselves. If the outfalls had been a few miles downstream it is possible that the Thames would never have become lifeless. Although the situation had improved by the beginning of the twentieth century, two world wars, and the continued growth of population in the London area without adequate provision for sewage treatment, meant that by the 1950s there were no established fish populations in the Thames over a distance of 69 km. Most of this stretch had extremely low dissolved oxygen concentrations, the consequence of the massive organic pollution.

This intolerable state was recognized and major improvements in sewage treatment started. The effect of these improvements on the fish fauna was monitored in an original way. Wheeler arranged for the collection of fish caught on the filter screens of electricity generating stations which extracted cooling water from the Thames. These collections yielded a clear picture of the recovery of the fish fauna, as both the number of species and the number of individuals increased. This picture of a cleaner river was emphasized dramatically when salmon were recorded in the Thames for the first time in 140 years.

The second half of the book is a detailed description of the results of Wheeler's and other collections made since 1967, in which 72 species were recorded. This section makes difficult reading. Much of the

quantitative data could have been relegated to an appendix for, as Wheeler himself notes, the method of collection provided a qualitative rather than quantitative picture of the recovery of the fish fauna. Yet some of the detail is inadequate: for some species inadequate morphological detail is given; and authorities are not given for the specific names while some common names are used inconsistently.

Finally, Wheeler notes that a cleaner river is more sensitive to environmental disturbances which would have been insignificant when the river was lifeless. Potential hazards include the effects of large power stations on water temperature and hence dissolved oxygen, the discharge of raw sewage during storm overflow, and the effects of flood prevention schemes. Although it is unlikely that commercial fishing will again flourish in the tidal Thames, the aesthetic and recreational benefits provided by established fish populations are incalculable. Wheeler's book illustrates how effective public spending, which is now under attack, can be in a civilized, industrialized state.

Although there are a few typographical errors and mistakes of chronology, the book is reasonably priced. Many of the illustrations are taken from Yarrell's *British Fishes* (1859), which links Wheeler's book with that of a naturalist familiar with the Thames before it died of pollution. □

Today immunology is moving fast. From its origins in microbiology it has become both an independent science and a tool of many disciplines. As more of the skills of molecular biology become absorbed, its growth is quickening still further.

For people active in immunology, keeping pace with research now means a time consuming search through very many major journals for the scattered results and conclusions of real significance.

Maintaining an integrated, overall view of immunology is even harder.

That's why Immunology Today is such an important new publication: it will regularly provide an expert and critical synthesis of what is new and exciting in all branches of basic and applied immunology; it will speed the flow of accurate information throughout these areas of vigorous research.

In a monthly magazine format, Immunology Today will combine concise, impartial, up-to-date reviews and short, specialist commentaries on recent important findings, discussion of techniques, book reviews, highlights of workshop and conference proceedings, a reader's forum and news. Its scientific and clinical content will be guided by a distinguished advisory editorial board.

The first issue of Immunology Today will be published in July and will be distributed at the 4th International Congress of Immunology in Paris, July 21-26 1980.

Surprise!

J.S. Bell

Surprises in Theoretical Physics. By R. Peierls. Pp.166. (Princeton University Press: Princeton, 1979.) Hardback \$19, £8.40; paperback \$5, £2.10.

THIS is a fascinating book. About thirty situations are presented, scattered widely over theoretical physics. The surprise is sometimes that the obvious answer is wrong, sometimes that the devastating criticism of the obvious answer is wrong, sometimes that a very great man has gone wrong, and so on. Some of the surprises are pleasant, as with the validity of the nuclear shell model, or with the simplicity of Landau's diamagnetism. Some of the surprises are unpleasant, as with the non-existence of the Bogolyubov expansion for the diffusion coefficient, or even with the difficulty of estimating the adequacy of the JWKB method in barrier penetration. Some of the distinguished men who slipped up were very distinguished indeed. Debye was quite wrong about thermal conductivity in non-metals, and the "reasonable agreement with experiment fortuitous". Heisenberg was wrong about the resolving power of his γ -ray microscope, and was corrected by Bohr. Einstein forgot his own gravitational redshift in an attack on the time-energy uncertainty relation, and he also was corrected by Bohr. But Peierls himself remains surprised that Bohm and Aharonov have successfully attacked a version of this "fourth uncertainty relation". He conjectures that the interaction they invoke "for some reason cannot be permitted in quantum mechanics".

Sometimes the important reference is to early work of Peierls himself. It is the 'Umklapp' process of his 1929 thesis which resolves the difficulty with Debye's thermal conductivity. Sometimes the surprise has been generated by colleagues in his own department. But the choice is catholic, and indeed the two longest sections in the book are concerned with two perennial surprises — irreversibility in statistical mechanics, and the problem of interpreting quantum mechanics.

It seems to me that the non-technical account of macroscopic irreversibility, contrasted with microscopic reversibility, brings out admirably the essential point often concealed in lengthier and more mathematical accounts. That is to say that the situation is intelligible when we suppose boundary conditions to be imposed in the past, rather than the future, and with no great care — or at least without the fantastic and conspiratorial care that could have ensured the exceptional decrease of entropy rather than the normal increase.

As regards the problems of quantum mechanics, Peierls begins with an account

of what went wrong with the celebrated von Neumann theorem on the impossibility of deterministic hidden variables. He continues with a nicely ironical account of subsequent work centred on the notion of 'locality'. Then he takes up the infamous 'reduction of the wave packet'. To my dismay he regards it as "clear that the significance of the state function is to represent our state of knowledge of the system". But he goes on to ask "whose knowledge . . .", and is carried down into the depths. He finally conjectures that the Schrödinger equation does not apply to conscious organisms and (if I interpret correctly) that it is in the presence of such organisms that linearity fails and wave function collapse occurs. It seems to me that the reduction is then dynamical rather than actuarial. It is not at all to be equated with the mere adjustment of odds appropriate when a candidate for life insurance is seen to be over one hundred.

The bulk of the book is occupied with quantum and statistical mechanics. But finally there is one relativity problem. It is the old question of radiation — or non-radiation — from a uniformly accelerated charge. Here (surprise) there is something quite new, from unpublished work of Boulware. He has worked out carefully (for the first time, it seems) how it looks in the accelerated system in which the charge is at rest. I would have liked to have seen my favourite relativity surprise included in this book. I will yield here to the temptation to describe it (A. Evett, *Am. J. Phys.* **40**, 1170; 1972). Two identical spaceships,

identically programmed, are initially at rest in some inertial system S, one of them 100 metres behind the other. At a given moment (in S) both motors start and off they go. With identical acceleration programmes they remain, of course, always 100 metres displaced from one another (in S). The ships are initially connected by a fragile (but incombustible!) thread. This thread would like to Fitzgerald — contract as the ships speed up, but as they do not come closer (in S) the thread cannot contract — so it breaks. Or does it? My experiences with this puzzle have convinced me that most relativity courses seriously damage the minds of most students.

There are no surprises here from elementary particle theory. Is that, then, only a dull plodding sort of subject? I think not. For example, there was the big surprise of a renormalizable theory of weak interactions. And I think also of the very beautiful surprise of the 't Hooft-Poynakoff magnetic monopole. And surely there are many others.

But let us be grateful for what we do find in this excellent book. One of the nicest surprises in it is the elegant simplicity with which nearly all of these topics are presented. The essays are mostly accessible to undergraduates with a first course in quantum mechanics, and to graduates who have not forgotten. □

Memorial to the Ghetto

John Rivers

Hunger Disease. Edited by Myron Winick. Pp.261. (Wiley: New York and Chichester, UK, 1979.) \$19.80, £10.60.

THIS is an important book. It was conceived of early in 1942 by Dr Israel Milejowski who, as chief of public health in the Warsaw Ghetto, was sure that death from starvation and disease awaited its inhabitants. Certain of this fate, and powerless to prevent it, he recruited 27 colleagues and persuaded them to undertake a scientific study of the effects of hunger that they were observing in the Ghetto. Such a study, he hoped, would be, at least, a memorial to the dead.

They had just five months to build that memorial. On 22 July 1942 the German authorities began to liquidate the Ghetto and its inhabitants. Milejowski records that their already meagre hospital and laboratory facilities were destroyed, and, with mass deportations occurring around them, the scientists wrote up their work

and prepared the manuscript that was smuggled out of the Ghetto and hidden.

It was a remarkable feat, but ironically it almost seemed as if their efforts were in vain. Though the manuscript survived the war, only limited editions were published in Polish and French, and though the title *Maladie de Famine* was often referred to in the nutrition literature, the document itself was largely unread by nutritionists.

In rescuing it from obscurity, and producing not only an English translation, but a detailed appreciation of the modern significance of the work, Professor Winick has ensured that the memorial Milejowski intended has at last been built.

But the book must not be viewed as a purely historical document, and Professor Winick has wisely treated it as a work of current scientific merit. Of course it is a strange scientific document, exploring theories and using techniques of 40 years ago. But outmoded or not it is still of current interest, because, with the exception of Keys' *Biology of Human Starvation* (University of Minnesota Press, 1950), it is the only study in the field. Though by its brevity it is less authoritative than Keys' work, it ranks alongside it as a scientific document because it deals with some different aspects of starvation, and

Severe marasmus and death in the Warsaw Ghetto.

because, unlike Keys' experimental study, it deals with people starving to death.

I am sure that many of the results the authors obtained will still be of scientific interest.

For example, the chapter by Fliederbaum *et al.* on metabolic changes records that in severely malnourished patients BMR was 30–40% below normal and was not stimulated by protein feeding, but increased by 20–50% when sugar was fed. Or again, Fajgenblat's brief report on ocular changes in starvation, or Apfelbaum-Kiwalski's report on the pathophysiology of the circulatory system in starvation, will be read with interest by all workers in the field. All will, like me, be saddened by the brevity of the reports: in reading the book I often found myself wishing that all the authors had reported their raw data, or referenced the exact methods by which they worked out complex indices (like the degree of normality of BMR) but, given the conditions in which they worked, one can only be grateful that anything at all has survived.

That which has survived will be accorded a place of honour amongst many analogous nutritional studies on the pathophysiology of protein-energy malnutrition in children that have been produced since the Second World War.

However there will remain one crucial difference between this book and many other postwar studies on the biochemistry of malnutrition. Most scientists studying malnutrition since the war have done so because they believed that the causes and cures of malnutrition should be sought at

the physiological level. The authors of this book had no such illusion. The cause of the malnutrition they describe is to them clear: it is the result of a systematic policy which, in isolating the Jews from the economic life of the nation, sentenced them to death. It was a policy which allowed a Jew only 800 kcal per day, under half of that allowed by the Germans even for people who did no work worth mentioning. It was in response to this policy that the authors undertook their study, not because they believed they would find a scientific cure for the Hunger Disease that this policy induced, but because all they could do as scientists was to create a memorial to the dead, by their contribution to scientific knowledge.

Is there in this a lesson for our times? In the 40 years since the Ghetto was destroyed, immense scientific effort has been put into studies of the nutritional and metabolic aspects of protein-energy malnutrition in children without doing anything to reduce the prevalence of the disease. Perhaps the heroic efforts of Milejowski and his colleagues should cause us now to focus more clearly on the cause of the disease and step outside a narrow scientific paradigm to seek a cure.

John Rivers is a Lecturer in the Department of Human Nutrition at the London School of Hygiene and Tropical Medicine, University of London, UK.

O polish'd perturbation

A.J. Meadows

Planets X and Pluto. By William G. Hoyt. Pp.302. (University of Arizona Press: Tucson, Arizona, 1980.) Hardback \$17.50; paperback \$9.50.

A YEAR from now we will be celebrating the two-hundredth anniversary of the discovery of the planet Uranus by William Herschel. Compared with, say, the Einstein centenary which occurred recently this might seem to be an event of limited interest. In terms of its contemporary impact, however, Herschel's discovery attracted as much public attention as the General Theory of Relativity did in this century. For the first time since prehistory, the scope of the Solar System had been enlarged. The natural reaction of astronomers was to look for other, as yet undiscovered, planets — a hunt which lasted for a century and a half.

Mr Hoyt's book is primarily concerned with the investigations that led to the last of these planetary discoveries — the detection of Pluto. But it is logical that he should introduce this search with a detailed discussion of the events surrounding the discovery of earlier planets before turning to Pluto itself. His account is readable, but highly detailed. Like his earlier book,

Lowell and Mars, the narrative is partly based on material in the Lowell archives. Like the earlier book, too, it is intended as a partial history of the Lowell Observatory, and so covers matters other than planets. But it is the search for Planet X — as the supposed planet beyond Neptune was labelled — that dominates the story.

The main outlines of the hunt for new planets is fairly familiar, at least up to the discovery of Neptune. But this earlier history — and especially the problems facing the theoretical prediction of Neptune's position in the sky — provides a fascinating parallel with the subsequent search for Planet X. Neptune was sought because the newly discovered Uranus stubbornly refused to follow its predicted path. The postulate of an outer planet, gravitationally perturbing Uranus, became an increasingly attractive possibility. Ultimately, two theoretical astronomers, Leverrier and Adams, independently predicted a position for this supposed planet. Their results were in good agreement with each other, and Neptune was, indeed, picked up close to the predicted point. So far, this was a major success story. But it rapidly became evident that some of the assumptions made by both Leverrier and Adams in determining the new planet's position were far removed from reality. How, then, had they managed to pinpoint its place so accurately? It was very quickly suggested that their result was purely a 'happy

accident', a conclusion which was equally quickly denied. The controversy continues today (it is, perhaps, a slight defect in this book that the subsequent analyses of the problem are not fully covered); but a modern consensus would give Leverrier and Adams the benefit of the doubt.

The search for Planet X possessed one immediate difference from the hunt for Neptune. Like the latter it was based on an examination of residuals, otherwise unaccounted for, in the orbits of the inner planets (in this case, Uranus and Neptune). The residuals now, however, were much smaller than those that had originally attracted attention to the existence of Neptune. It was less that these residuals forced a search for a new planet than that the desire to find a new planet motivated the investigation of the residuals.

The most detailed, though not the only, attack on the problem of Planet X was by Percival Lowell, and much of the book revolves round his activities. Lowell's final predictions appeared in 1915 — only a year before his death — but the astronomers at Lowell Observatory had already started on a photographic search for the supposed planet in 1905. After Lowell's death the search lapsed, only to be resumed at the end of the 1920s. It was then undertaken by Tombaugh, a new recruit to the observatory staff, and, early in 1930, he discovered Pluto close to the point indicated by Lowell's calculations.

This sounds like a repeat of the

successful hunt for Neptune. The similarity extends even further, for one of Lowell's contemporaries, W. H. Pickering, had predicted the existence of a planet at about the same place as that suggested by Lowell. (The parallel with Leverrier and Adams cannot be pushed too far, however, for Pickering enthusiastically predicted the existence of several planets at various distances from the Sun.) There was one major difficulty: both Lowell and Pickering supposed in their calculations that Planet X must be a reasonably massive body. Pluto, when found, proved to be fainter, and so presumably smaller, than expected. Was it really the predicted planet? The arguments started once again:

rather unproductively this time, because no mass was available for Pluto. The climax both of this dispute and of the book has actually only just occurred: for, in 1978, a Plutonian satellite was finally discovered. The consequences are remarkable — to quote Mr. Hoyt:

"The discovery of a Plutonian satellite [named Charon], of course, permitted the first direct and reasonably accurate determination of Pluto's mass since the planet's discovery forty-eight years ago . . . Pluto is thus a very, very small planet indeed, only about 20 percent as massive as the earth's moon, and with a probable diameter of only 1500 miles (2420 km), about two-thirds that of the earth's moon.

"The discovery of Charon, and the consequent determination of Pluto's very small mass, made it certain that Pluto could not be Percival Lowell's predicted Planet X, and thus the long controversy over this question ended."

The result is stated firmly; but it leads to the very odd conclusion that the positions of Pluto (certainly) and Neptune (possibly) were correctly predicted by accident. The Einstein centenary reminded us that God does not play dice. Perhaps the Uranus bicentenary should assure us that He does.

A.J. Meadows is Professor of Astronomy and History of Science at the University of Leicester, UK.

New astronomies

R.J. Tayler

A Source Book in Astronomy and Astrophysics, 1900-1975. Edited by K.R. Lang and O. Gingerich. Pp.922. (Harvard University Press: Cambridge, Massachusetts, and London, UK, 1980.) \$50.

THIS book provides an attractive invitation to review the great increase in our knowledge of the Universe over the present century. In 1900, most astronomers believed that the Milky Way system was the whole Universe and that the Sun was near its centre. The existence of interstellar matter was suspected but not established and it was not known that interstellar dust absorbed starlight and produced a seriously biased view of the Universe. Although spectroscopy had shown that stars contain the same chemical elements as the Earth, a quantitative discussion was impossible because the structure of atoms and the origin of spectral lines were not understood. A study of stellar structure had started but its further development required more knowledge of atomic physics and of nuclear structure, leading to an explanation of the source of stellar energy.

For the first two-thirds of the period under review, observational advances were restricted to optical astronomy. The Universe was seen to be an immense expanding system of galaxies and the structure of our Galaxy and its constituent stars and gas clouds was studied in great detail. Towards the end of this great period of optical astronomy, many astronomers believed that all the important components of the Universe had been discovered. This view has been transformed in the past twenty-five years by the development of new astronomies — radio, infrared, ultraviolet, X-ray and γ -ray — studying the 'invisible Universe', and by the discovery, for example, of quasars, pulsars, X-ray binaries, interstellar neutral hydrogen and molecules and the cosmic microwave radiation. Theoreticians have

used developments in physics, such as quantum theory and general relativity, to explain the properties of objects already known and to predict the existence of new types of object.

Drs Lang and Gingerich have selected about 150 key papers to trace the increase in our knowledge. In some cases the papers are printed in full and in others the less essential parts of the discussion have been paraphrased. In every instance, they have introduced their selection by some general remarks on the development of the subject; this enables them to give due credit for key work which they could not include in the anthology. I find this a fascinating collection of papers and I am impressed by

the quality of the editorial work. In reading the book, I have learnt many things which I had not previously known and others which I had forgotten. The book should certainly be widely available to both young and old students of astronomy. It is inevitable that not all astronomers will agree with the choice of key papers. In general, I did find what I expected but I was surprised that, although the work of Chandrasekhar is widely quoted, not one of his papers is included and I would have included Parker's paper on the solar wind.

R.J. Tayler is Professor of Astronomy and Director of the Astronomy Centre at the University of Sussex, Brighton, UK.

CONTINUING CHANGE IN SCIENTIFIC THOUGHT

The Mystery of DNA Replication

An intriguing story of the ways in which science is carried out—how scientists begin from pre-conceived notions that must be adjusted to conform to the facts confronted in nature.

By Karl G. Lark

Recent breakthroughs in the understanding of DNA replication have involved reassessment of conclusions, new understanding of the way in which genetic material may operate, and a whole new set of "prejudices." This book tells of a most exciting period in genetic research and predicts its significance for the next years of discovery.

text books from MACMILLAN PRESS

ORBITALS & SYMMETRY D. S. URCH

This book introduces both symmetry and molecular orbital theory in one volume. The mathematics which chemists need to apply to symmetry ideas is developed using molecular examples, (rather than abstract mathematical ones). At all stages worked problems are given in the text and further exercises are set at the end of each chapter.

The aim has been to give the reader a critical appreciation of two very important aspects of theoretical chemistry, molecular orbital theory and symmetry, and to show him how to apply them to a wide range of chemical problems.
1979, £4.95, 0 333 26675 7

CHEMISTRY FOR THE LIFE SCIENCES

Second Edition

J. C. DAWBER and
A. T. MOORE

The book is primarily designed as an integrated chemistry text for undergraduate students on degree courses in biology, biochemistry, pharmacy, and medicine at universities, polytechnics, and colleges of higher education.

It will also serve as a text for HNC and HND students in Applied Biology and Medical Laboratory subjects, and students studying for MIBiol. and Membership of the Institute of Medical Laboratory Technicians. Students on joint honours courses (e.g., Combined Science) in which biology is a major subject will find the book useful.

February, £16.00, 0 333 25820 7
£8.95, 0 333 25821 5

PLANT METABOLISM

H. D. KUMAR and
H. N. SINGH

The highly complicated, interconnected metabolic cycles that continue unceasingly within the living cells of plants are refreshingly simplified in this classic text for students of botany and those studying agricultural botany and plant physiology in agricultural colleges.

The physiologist, the biochemist, and the phytochemist — each will find his particular field ably covered in this masterful analysis which integrates the different features of plant chemicals — their potential functions, their synthesis and degradation — into a comprehensive account.

February, £4.95, 0 333 25638 7
